## ABSTRACT

In 1982, the National Marine Fisheries Service, under contract to the Bonneville Power Administration, began a 5-year study to determine if serially releasing steelhead, Salmo gairdneri, smolts over a 40-day period and transporting them by barge to a release site in the Columbia River below Bonneville Dam would result in increased returns of adults to Dworshak National Fish Hatchery.

Over 252,000 smolts were marked for the study; about 30,000 fish for each of five test lots (transported) and three control lots (released into the Clearwater River at the hatchery). Serial releases of test fish (barged to the Columbia River below Bonneville Dam) were made on 19 April, 30 April, 19 May, and 31 May 1982. Paired control groups (fish released as normal hatchery production into the Clearwater River) were released with the first three tests. In the interest of marking fewer fish, no control group was released with the last test.

Recoveries of control releases at dams along the migration route indicated a high survival to Lower Granite Dam and a low survival from there to John Day Dam. Approximately 57% of the control releases were transported from collector dams (Lower Granite, Little Goose, and McNary), as part of the routine transportation program.

The health and status of smoltification for the juvenile fish were monitored from mid-March to the release date for each group. This phase of the study was conducted under subcontract to the University of Idaho, Moscow, Idaho. The fish sampled were generally determined to be clinically healthy.

Final evaluation of the study will be based on the numbers of adults returning in ensuing years to Columbia River fisheries; adult collector points at Bonneville, McNary, and Lower Granite Dams; fisheries in Idaho; and the Dworshak National Fish Hatchery.

## INTRODUCTION

In 1982, the National Marine Fisheries Service (NMFS) began a 5-year study under contract to the Bonneville Power Administration (BPA) to determine if transporting steelhead, Salmo gairdneri, smolts directly from Dworshak National Fish Hatchery (NFH) to the Columbia River below Bonneville Dam by barge would increase returns of adults to the hatchery and the fishery.

Impetus for the study came from a test conducted in 1978 at Dworshak NFH in which substantially more adults returned to the hatchery and nearby sport fishing areas from a group of smolts that were barged from the hatchery and released below Bonneville Dam than returned from similar groups trucked to below Bonneville Dam or released at the hatchery to migrate downriver on their own volition (Slatick et al. 1982).

Slatick's data suggest that transportation of fish directly from Dworshak NFH enhanced returns of adults to the hatchery and to the sport fishery. His results, though, were based on only one release group at one point in time. Barging of a substantial portion of the hatchery production, however, would take between 30 and 40 days. Before implementing such a program, the management agencies need to know whether steelhead smolts transported throughout a 30-to 40-day period in April and May would return in greater numbers than nontransported smolts. NMFS' 5-year study was designed to provide the needed information.

Our major objective is to determine if groups of steelhead that were reared and imprinted at Dworshak NFH and then transported by truck to a transfer site near Lewiston, Idaho; released into barges; transported via barge to a release site in the Columbia River below Bonneville Dam; and

released will produce a greater percentage of returning adults to the hatchery and to the fishery in Idaho than fish released directly into the river at the hatchery. The groups of fish were scheduled for transportation during a 40-day period (serial releases). Incidental to measuring the benefits of transportation, we will determine the proportion of fish in each serial release that have accepted a homing imprint. We will also monitor fish health and smoltification throughout the test period. This initial report summarizes our research in 1982.

#### PROCEDURES

The experiment involved marking eight separately identifiable groups of about 30,000 steelhead each (five test and three control groups) (Table 1). Fish for marking were taken from eight ponds in System II (a reuse water system) at Dworshak NFH. All fish in these ponds were progeny of fish spawned on the same day in the spring of 1981 (Egg Take 8). Total fish in the marking ponds and the size (fish per pound and mean length) and condition factor of the fish at time of release are given in Table 2.

From 23 February to 12 March 1982, 252,079 steelhead were marked with an adipose fin excision and injection of a coded magnetic wire tag (Table 1). Fish were also externally marked with a thermal brand so their progress as juveniles and as returning adults could be monitored at key sampling sites along their migration route without sacrificing the fish.

All test and control groups (except T1A) were reared on reuse water in System II at 48°F until 15 April 1982, then the water temperature was reduced to ambient (42°F) and the fish were held for 5 days. On 20 April 1982, System II was switched from reuse to raw North Fork Clearwater River water at **42°F**.

Table 1. --Steelehad marked in 1982 at Dworshak National Fish Hatchery.

Test (T4)	34,966	4,371	8.0	181	0.96

<sup>a/</sup> Condition factor--K-factor =  $\frac{\text{wt (gm)} \times 100,000}{\text{length (mm)}^3}$

Fish for Test T1A were reared on reuse water until 13 April 1982 when they were pumped from the reuse water pond (48°F) in System II to raw North Fork Clearwater River water (40°F) in another pond in System III and held for 6 days before being transported on 19 April to the barge at Lewiston, Idaho. Pumping of this test group to an alternate pond was required to duplicate the successful test treatment in the 1978 Dworshak NFH experiment (Slatick et al. 1982).

All test groups were loaded directly into fish transport trucks via fish pumps and transported to Lewiston, Idaho, on the Clearwater River (approximately 40 miles downstream) where they were off-loaded into a fish transport barge and held in recirculated Clearwater River water for approximately 16 h. The barge then traveled downstream with stops at Lower Granite, Little Goose, and McNary Dams to load fish as part of the transport program operated by the U.S. Army Corps of Engineers (CofE) (Figure 1) (Basham et al. 1983). Fish were released during darkness into the Columbia River below Bonneville Dam at Skamania Light (RM 140).

Serial releases of test fish (barged to below Bonneville Dam) were made on 19 April, 30 April, 19 May, and 31 May 1982 (Table 1). Paired control groups (fish released as normal hatchery production into the Clearwater River) were released with the first three tests. In the interest of marking fewer fish, no control group was released with the last test.

The general health and status of smoltification of each experimental group were monitored from mid March until they were released from the hatchery. This portion of the project was carried out under subcontract to the University of Idaho (U of I), Moscow, Idaho 83843.

## RESULTS

### Recapture of Smolts at Dams and in the Estuary

Juveniles from control groups released at the hatchery were monitored at Lower Granite, McNary, and John Day Dams to determine their estimated passage and survival and the number of fish transported in the CofE operation. According to Sims et al. (1983), a high percentage of the control releases reached Lower Granite Dam, and a high percentage were subsequently transported (Table 3). The estimated survival of steelhead for the three control releases to Lower Granite Dam was near 100%, and overall, 57% were transported from Lower Granite, Little Goose, and McNary Dams. Survival of the nontransported controls to John Day Dam was only 1.9 to 3.4%--based on estimated passage of 2,390 fish at John Day Dam out of the 39,497 marked fish that were not collected and transported (Table 3). The apparent low survival of nontransported controls and large numbers of transported controls means that most of the controls that will be returning as adults will be those previously transported as juveniles. It is, therefore, likely that transport benefits shown for test fish will not be substantial.

A summary of recoveries from estuary sampling (Jones Beach, Oregon) is presented in Table 4. Dawley et al. (1983) indicate that recoveries of fish from test and control releases of the third and fourth treatment groups (released on 19 May and 31 May 1982) were substantially higher than from earlier releases of the first and second treatment groups (released on 19 April and 30 April 1982).

### Adult Returns

The first recoveries of marked experimental fish returning as adults are expected in the fall of 1983. Returning adults will be sampled at the in-river sampling facilities located at Bonneville, McNary, and Lower Granite Dams. The marked adults will be identified as to treatment groups by their brands; they will then be jaw-tagged and released to provide additional information at upriver recovery areas. An intensive sampling effort will be conducted on the Indian fishery (Columbia River Zone 6), sport fishery, hatcheries, and at the Dworshak NFH homing site. ~~This~~ sampling effort will be coordinated with state and federal sampling agencies for maximum recovery efficiency.

The adult return data from these experiments will be collected in the form of counts; discrete multivariate analysis will be used to statistically compare test and control treatments (Bishop et al. 1975). In this procedure, the treatments are structured as contingency tables, and significance is determined by the chi-square statistic.

### Juvenile Fish Health and Smoltification

The investigators from the U of I concluded that based on physical, physiological, and histopathological observations, there was no reason to assume that the fish sampled were anything other than clinically healthy. The complete report of studies is presented in Appendix A.

Juvenile smoltification analyses based on gill  $\text{Na}^+\text{-K}^+$  ATPase levels were also reviewed in the U of I report. Unfortunately, two sample groups of tissue were treated erroneously, resulting in questionable data which may compromise conclusions drawn from  $\text{Na}^+\text{-K}^+$  ATPase studies in 1982.

## SUMMARY

1. In 1982, a 5-year study was initiated to determine if steelhead smolts from Dworshak NFH that were transported downriver by barge and released below Bonneville Dam would contribute a higher percentage of returning adults than smolts released at the hatchery to migrate downriver of their own volition.

2. The first year of research concentrated on marking and releasing 252,079 steelhead smolts. A total of five barge transport test groups and three paired control groups of approximately 30,000 fish each were marked and released at about 10-day intervals.

3. A significant number of the controls were transported to below Bonneville Dam by the routine CofE transportation operations at Lower Granite, Little Goose, and McNary Dams. Recoveries of control fish at Lower Granite, McNary, and John Day Dams indicated a high survival rate to Lower Granite Dam and a low survival of the nontransported fish from there to John Day Dam. As a result, very few actual controls (those not transported) are therefore predicted to be returning as adults. This will be an important consideration when calculating transport benefits based on returning adults. Estuary recaptures suggest that survival and movement rates were higher for the fish released late in the season (released on 19 May and 31 May 1982) than for those released early in the season (19 April and 30 April).

4. The general health of each marked group of fish was monitored through analyses of body measurements: Na<sup>+</sup>-K<sup>+</sup> ATPase levels in gill tissues; prevalence of Renibacterium salmoninarum in kidney tissues; and

the histopathological conditions existing in the gill, olfactory, and optic tissues. The fish sampled were generally determined to be clinically healthy.

#### **ACKNOWLEDGMENTS**

Support for this research came from the Pacific Northwest's electrical ratepayers through the Bonneville Power Administration.

#### INTRODUCTION:

This report covers work performed under Contract No. 41 USC 252 (c) (3) during the period 3 March 1982 through 30 September 1982.

#### OBJECTIVE:

The objective of the study was to assess the general condition of health in groups of juvenile steelhead trout smolts released at intervals from the Dworshak National Fish Hatchery, Ahsaka, Idaho, during the period 23 March 1982 through 28 May 1982. The general condition of health was to be assessed through the following analyses: body (forklength) measurements;  $\text{Na}^{+}\text{-K}^{+}$  ATPase levels in gill tissues; prevalence of Renibacterium salmoninarum in posterior kidney tissues; and the histopathological conditions existing in the gill, olfactory, and optic tissues.

#### SAMPLING METHODS:

##### 1) Identification of Sample Groups:

Eight groups of fish were identified for the 1982 sampling. All groups were from egg take #8 of the 1981 brood, North Fork Clear-water strain of steelhead trout. The eight groups were divided into test and control lots, identified by a freeze-brand, and further divided into four release groups (Table 1). The established release dates were 19 April 1982, 30 April 1982, 19 May 1982, and 31 May 1982. All groups were in System II ponds at Dworshak NFH.

##### 2) Sampling Collection and Preparation:

A sampling schedule and sequence were established (Table 2). At sampling time, the required number of fish were selected at random from the designated pond by a dip net and placed into a bucket of water. The fish

<b>8</b>					<b>30</b>	

were taken to the facility laboratory and anesthetized in MS-222 (tricaine methanesulfonate, Ayerst Laboratories). Individual fish were measured (fork length to the nearest mm) and exsanguinated by caudal penduncle severance. The first right gill arch was removed, placed into a numbered vial containing an ATPase preserving solution and frozen in liquid nitrogen. The second right gill arch was removed and placed into a numbered vial containing 10% neutral buffered formalin. Also, into the same vial was placed a portion of the posterior kidney and the head severed just posterior to the eyes. Another portion of the middle and posterior kidney was placed into a numbered plastic bag and frozen at -40°C for subsequent examination for R. salmoninarum, the causative agent of bacterial kidney disease (BKD).

The 3/23, 4/8, and 4/9 samples for gill Na<sup>+</sup>-K<sup>+</sup> ATPase levels were removed from the liquid nitrogen after 2-3 hours and stored in a Revco freezer at -25°F. The 4/19, 5/17 and 5/28 gill samples were frozen directly in the -25°F freezer.

The frozen gill samples were shipped in dry ice via Greyhound Bus Lines to the NMS Field Station at Cook, Washington (Table 3).

### 3) Histopathological Methods:

The formalin-fixed gill and kidney tissues were processed through the paraffin vacuum-embedding technique, sectioned at 5 microns and stained using the alum hematoxylin-eosin Y technique. The formalin-fixed heads were cut sagittally, decalcified, and prepared for staining as in the gill and kidney tissues. Most of the sections were stained using the alum hematoxylin-eosin Y technique, and some were stained using the alum hematoxylin-eosin-phloxine-B technique.

**Table 3:** Schedule for submitting frozen gill samples to the NMFS Cook Field Station.

Arrival date	Sample group	Sampling date
5/26/82	1	4/19
	4	3/23
	4	4/08
	4	5/17
	5	4/19
	6	4/19
6/17/82	4	5/28
7/02/82	2	4/29
	3	5/17
	4	4/19
	4	4/29
	7	4/29
	8	5/17

#### 4) Immunofluorescent Method:

On the day of examination, the frozen samples of kidney tissue were thawed. A section was removed and the cut surface imprinted on a slide and allowed to air-dry on a slide warmer at 60°C. Each imprint was overlaid with an amount of appropriately diluted anti-R. salmoninarum conjugated with fluorescein isothiocyanate serum (National Fisheries Research Center, Leestown, West Virginia). The slides were incubated in 100% humidified chambers for 15 minutes at room temperature (22-24°C), rinsed through two changes of phosphate buffered saline (pH 7.6) and through two changes of distilled water to remove the saline. After air-drying, the imprints were mounted with a PBS-glycerol medium and examined microscopically under oil immersion. A minimum of 20 fields per smear were examined, and the number of organisms per field recorded.

#### RESULTS:

##### 1) Water Temperature:

The water temperatures at the scheduled times decreased from 47.7°F (8.72°C) on 23 March to 41.8°F (5.44°C) on 28 May 1982 (Table 4).

---

Table 4: Water temperatures at the time of the 1982 fish samplings from Dworshak NFH.

<u>Date</u>	<u>Water temperature (°F)</u>
23 March	47.7
8 April	47.0
19 April	42.0
29 April	42.5
17 May	44.0
28 May	41.8

---

## 2) Fork Lengths:

The fork lengths (mm) of individual fish show a gradual increase with time (Table 5). This is especially evident when the mean fork lengths and range of fork lengths recorded in the Group 4 samples are examined (Tables 6 and 7).

## 3) ATPase Analyses:

The samples taken for Na<sup>+</sup>-K<sup>+</sup> ATPase levels in gill tissues were sent to the NMFS Field Station, Cook, Washington, in three shipments. The first, sent on 25 May 1982, was scheduled to arrive on 26 May 1982; however, it did not arrive until late the following day because of an error in routing during shipment. As a result, some of the samples were thawed and were unsuitable for ATPase determination. The specific samples unsuitable were from Group 4, the 3/23 and 4/8 samples.

In general, there was a gradual increase in gill Na<sup>+</sup>-K<sup>+</sup> ATPase levels during the overall sampling period (Tables 8 and 9).

## 4) Prevalence of Renibacterium salmoninarum:

Using the method of direct immunofluorescence, R. salmoninarum, the causative agent of BKD, was detected only in samples collected on 17 May 1982 (Table 10). Since the samples were examined at several points in time by sampling date, it is possible to assume that the reagent(s) were contaminated with R. salmoninarum at that point in time. ~~This~~ assumption is somewhat validated by not detecting the organism in any other samplings of Group 4--before or after the 17 May sample. It is further validated by closely examining the histopathological sections of the specific fish involved and not detecting any evidence of pre-clinical BKD.

Table 6: Average fork lengths (mm), range (mm), and standard deviations of lengths in sample groups of fish at Dworshak NFH.

Lot no.	Sampling date	Mean length (mm)	Length range (mm)	Standard deviation

#### 5) Histopathological Examinations:

In general, there were no significant life-compromising histopathological changes observed in gills, kidneys, nasal sac, and post-orbital tissues (Table 11). The most consistent finding in the gill tissues was a mild to moderate lamellar hypertrophy, to which no clinical significance was attached. In one sampling (Group 4 on 4/19), there were several fish exhibiting lamellar necrosis. The clinical significance of this is unknown, but given the general histopathological conditions of the kidney, nasal, sac, and post-orbit tissues, it is unlikely that the gill condition was anything more than transitory.

The most consistent finding in the kidney tissues was a mild to moderate generalized fatty infiltration which was probably due more to dietary composition rather than to renal dysfunction, given the condition of the renal tubules and glomeruli. There were isolated instances of mild to moderate hydropic changes in the renal tubules, but no clinical significance was attached to this given the lack of more serious lesions in the renal tissues.

The nasal sac and post-orbit tissues were consistently without abnormalities. The observations of free blood in the nasal cavities of some samples was probably due to hemorrhage induced through sampling technique because the underlying tissue were without notable degenerative changes.

#### CONCLUSIONS:

Based upon the foregoing physical, physiological, and histopathological observations, there is no reason to assume that the fish sampled were anything other than clinically healthy. Throughout the 420

Table 11: Histopathological changes in gill, kidney, nasal sac, and post-orbital tissues of steelhead sampled in 1982 from Dworshak N. F. H.

Group No.	Sampling Date	Observations
1	4/19	<p>Gills: Occasional mild epithelial-capillary separation and lamellar hypertrophy.</p> <p>Kidney: Some hydropic change and fatty infiltration. The larger fish were more affected.</p> <p>Nasal sac: No abnormalities noted.</p> <p>Post-orbital: No abnormalities noted.</p>
2	4/29	<p>Gills: Generalized mild hypertrophy and epithelial-capillary separation. Occasional mild to moderate lamellar engorgement.</p> <p>Kidney: Mild fatty infiltration.</p> <p>Nasal sac: Some free blood in nasal cavity (sampling technique?)</p> <p>Post-orbital: No abnormalities noted.</p>
3	5/17	<p>Gills: Generalized mild to moderate hypertrophy. Occasional focal hyperplasia and lamellar congestion.</p> <p>Kidney: Focal hydropic change.</p> <p>Nasal sac: No abnormalities noted.</p> <p>Post-orbit: No abnormalities noted.</p>
4	3/23	<p>Gills: Generalized mild lamellar hypertrophy.</p> <p>Kidney: Mild fatty infiltration.</p> <p>Nasal sac: No abnormalities noted.</p> <p>Post-orbit: No abnormalities noted.</p>

Table 11: Continued

Group No.	Sampling Date	Observations
4	4/8	Gills: Generalized mild lamellar hypertrophy. Mild epithelial-capillary separation. Kidney: Mild fatty infiltration and hydropic change. Nasal sac: Some free blood in nasal cavity. Post orbit: No abnormalities noted.
	4/19	Gills: Mild terminal lamellar hypertrophy. Focal areas of lamellar necrosis with and without hemorrhage. Kidney: Mild to moderate fatty infiltration. Nasal sac: Free blood in nasal cavity. Post-orbit: Free blood in retro-orbital space.
	4/29	Gills: Mild focal terminal lamellar hypertrophy. Kidney: Mild fatty infiltration and hydropic change. Nasal sac: No abnormalities noted. Post-orbit: No abnormalities noted.
	5/17	Gills: Mild generalized lamellar hypertrophy. Occasional epithelial-capillary separation. Kidney: Mild fatty infiltration. Nasal sac: No abnormalities noted. Post-orbit: No abnormalities noted.
	5/28	Gills: Mild generalized lamellar hypertrophy. Occasional lamellar hyperplasia. Kidney: No abnormalities noted except in two samples - one with marked renal tubular necrosis and one with intratubular crystals. Nasal sac: No abnormalities noted. Post-orbit: No abnormalities noted.

Table 11: Continued

Group No.	Sampling Date	Observations
5	4/19	<p>Gills: Mild to moderate generalized lamellar hypertrophy. Occasional lamellar engorgement and lamellar hyperplasia.</p> <p>Kidney: Mild to moderate fatty infiltration and hydropic change.</p> <p>Nasal sac: No abnormalities noted.</p> <p>Post-orbit: No abnormalities noted.</p>
6	4/19	<p>Gills: Moderate lamellar necrosis with hemorrhage. One sample with a mild <u>Dermocystidium</u> infection.</p> <p>Kidney: Mild to moderate fatty infiltration and hydropic change.</p> <p>Nasal sac: Some samples with free blood in nasal cavity.</p> <p>Post-orbit: No abnormalities noted.</p>
7	4/29	<p>Gills: Mild generalized hypertrophy.</p> <p>Kidney: Mild generalized fatty infiltration.</p> <p>Nasal sac: No abnormalities noted.</p> <p>Post-orbit: No abnormalities noted.</p>
8	5/17	<p>Gills: Mild focal lamellar hypertrophy. Several fish with moderate epithelial capillary separation.</p> <p>Kidney: Mild generalized fatty infiltration.</p> <p>Nasal sac: No abnormalities noted.</p> <p>Post-orbit: No abnormalities noted.</p>

fish examined intensively, there was not a single indication of a potentially life-compromising condition. The gill tissues were in the best condition of any ever examined from a hatchery environment.

If there were one recommendation to be made from these observations, it would be to evaluate the influence of dietary composition and feeding rate on the presence of fatty infiltration in the kidney. Another suggestion would be to examine more fish from more facilities to gain a broader base of knowledge.
