Project No. 88-108
Contract No. **DE-FC79-89BP94402**

PREFACE

An essential component of the effort to rebuild the **Columbia** Basin's anadromous fish resources is that available information and experience be organized and shared among numerous organizations and individuals. Past experience and knowledge must form the basis for actions into the **future**. Much of this knowledge exists only in unpublished form in agency and **individual** files. Even that information which **is** published in the form of technical and contract reports receives only limited distribution and is often out of print and unavailable after a few years. Only a small fraction of the basin's collective knowledge is captured in permanent and readily available databases (such as the Northwest Environmental Database) or in recognized journals.

State, tribal, and federal fishery managers have recognized these information management problems and have committed to a program, the Coordinated Information System Project, to capture and share more easily the core data and other information upon which management decisions are based. That project has completed scoping and identification of key information needs and development of a project plan. Work performed under the CIS project will be coordinated with and extend information contained in the Northwest Environmental Database. Construction of prototype systems will begin in Phase 3.

This report is one in a series of seven describing the results of the Coordinated **Information** System scoping and needs identification phase. A brief description of each of these reports follows.

CIS Phase II Products

Phase II Summary Report

This report (Roger 1992) summarizes and integrates the results of the next five reports and relates them to deliverables identified in the Phase II cooperative agreement. Broader issues of organization and operation which are not appropriate for the more focused reports are also discussed. **This** report should be viewed as an executive summary for the CIS project to date. If one wants a quick overview of the CIS project, this report and the project plan will provide that perspective.

Report on Information Needs

This report (Weber et al. 1992) identifies the core information needed to plan, implement, monitor, and evaluate projects to **manage** and restore anadromous fish. This information has been organized into various categories and missing items are identified. Prototype testing in Phase 3 will focus on this core information.

Data Catalog Report

This report (O'Connor et al. 1992) might be thought of as a "yellow pages" directory describing relevant numeric data available throughout the basin. An easily searched electronic version will be developed during prototype development and the catalog will be maintained and expanded.

Technical and Administrative Options Report

This report (Allen et al. 1992) describes a process for implementing the CIS and feasible hardware, software, and operational options. Recommendations **are** made for the prototype and implementation phases of the project.

Library Resource Options Report

This report (**Roseberry** 1992) describes options for the size and operational features for the non-numeric portion of the CIS. Recommendations are made for the prototype and implementation phases.

Stock Summary Reports

These reports (Olsen et al. 1992; Hymer et al. 1992; Kiefer et al. 1992) are available in five separate volumes for Oregon (**2**), Washington (**2**), and Idaho (1). The reports contain basic biologic information on **anadromous** fish populations in the Columbia Basin. This information will be incorporated into computerized data bases during prototyping and implementation and will be updated annually.

Project Plan

The Project Plan (Roger et al. 1992) is derived directly from recommendations from the above reports. It describes anticipated activities, staff needs, and cost of the project for the testing and implementation phases.

ACKNOWLEDGEMENTS

Many thanks **are** due to the numerous people who contributed to the preparation of the information contained in this report. Those from the Washington Department of Fisheries included Lisa Harlan, Bob Woodard, Steve Campbell, **Bill** Kinney, Ken Keller, Wolf **Dammers**, and Dick O'Connor. Those from the Washington Department of Wildlife included Brodie Cox and Dan Fender. Helen Morrison and AM Roseberry of the Columbia River Inter-Tribal Fish Commission worked on the **draft** and **final** documents, and Phil Roger, CIS project leader, saw it through to completion.

INTRODUCTION

Purpose of the Report.

These volumes update the Stock Assessment Report (SAR) published in 1985 (Howell et al.). They have been enlarged partially in response to Northwest Power **Planning** Council comments concerning the 1985 report. The volumes are new in their format and an annual updating and **refining** of their information is anticipated. The volumes include both genetic information such as electrophoretic profiles, and non-genetic information. Non-genetic items include the abundance of populations, number of **smolts** released or outmigrating, and number of adults caught in the subbasin, etc.

The reports are divided into **subbasin** chapters composed of sections reporting the species of salmon and steelhead present, and their production type (natural and/or hatchery). Within each subbasin, the species are listed in the following order, if present:

- spring chinook
- summer chinook
- fall chinook
- coho**
- chum
- sockeye
- summer steelhead
- winter steelhead

Within each species, naturally produced fish are listed before hatchery produced fish and early run types before late run types.

It should not be presumed that the geographical scale of these units is of biological significance. The subbasins used were the same as those units **defined** in the Columbia Basin **Subbasin** Planning Process. Some agencies chose to summarize data in finer geographic sub-divisions. The use of the word "stock" in the title "Stock Summary Report" refers to these geographic **subbasin** units, and does not presuppose any evolutionary significance. As in the 1985 SAR, the information varies from specific conclusions based on substantial data, to general statements which have not been verified. The standards established and agreed upon by the contributors may have not yet been met in all categories by the authors.

Desired Qualities in Stock Assessment Data.

These data should be used with caution if used to compare **subbasin** populations. A description of how the data was collected and summarized follows in the methods section, and the reader is urged to contact the primary authors for further clarification.

The methods of comparing stock data may vary, but there are certain qualities such data should have. A calibration of the effects the environment has on the traits described would also give analyses more meaning. For example, the environmental influences of temperature, size and timing of release or outmigration, and harvest may all influence the observed age composition of a brood.

Life history differences between stocks should not be artifacts of year-to-year variations in abundance. This is one reason information was reported in the brood year format. Multiple year class data were reported so the magnitude of a trait's temporal variation might be assessed.

Brood Year Format

The **brood** year format was used in the majority of the standard tables as a way of **tracking** the progeny of a season's spawners (a cohort). For instance, 1987 brood **coho** salmon came from adults that spawned in the fall of 1987. As juveniles, these **coho** might not have migrated until the spring of 1989. The 1987 brood jacks (two year olds) returned and were accounted for in the fall of 1989. The remaining adults returned and were accounted for in 1990. Thus, a 1987 brood year entry in a **coho** table is in fact current through 1990 returns. Similarly, a complete accounting of a chinook salmon brood may take six years. In such a case, the 1984 brood would be the latest brood fully reportable with 1990 return year data (reporting up to the 1990 run year was **minimum** goal for these reports).

Authorship

Information contained in this volume represents the work of several agencies. The Washington Department of Wildlife (**WDW**) compiled the steelhead reports. The Washington Department of Fisheries (**WDF**) compiled the chinook, **coho**, sockeye, and chum **salmon** reports for all subbasins except the Yakima, which was compiled by Columbia River Inter-Tribal Fish Commission (CRITFC) staff. The views represented in this volume are those of the agencies compiling the information, and do not necessarily represent the views of other CIS participants. Portions of the information in this report are reported in standard formats developed by the CIS participants. CRITFC provided coordinating services to provide consistency among the five Stock Summary Report volumes. This report includes all data received from the agencies by September 30, 1992.

METHODS

Following Howell et al.'s methodology (1985), published and unpublished anadromous fish data derived from both a literature review and contacts with biologists and hatchery personnel were summarized by subbasin. This report includes all of that information which could be located and fit into a set of standardized tables. The agencies were free to **introduce** these tables in the order they found appropriate to the following major text headings:

Geographic Location

(A brief description of the subbasin)

Origin

(Source of broodstock or eggs for hatchery stocks, history of hatchery stock introductions)

Distribution

(The distribution of the species in the subbasin)

Production

Adult Life History

Juvenile Life History

Biochemical-Genetic Characteristics

Diseases

References

Ten categories of information based on the Northwest Power Planning Council comments on the 1985 SAR were addressed. A list of the standard tables developed to address these categories, and a key to the two letter codes used to identify them throughout the document, follows at the end of this section.

1. Species and Strain

Maps were used to depict spawning, rearing, and hatchery locations for at least one anadromous species per subbasin. A complete set of these maps may be found in the 1990 **Subbasin** Production Plans.

2. Timing of Runs

Charts also developed for the 1990 **Subbasin** Production Plans were used to depict the freshwater life history of the salmon and steelhead. Peak dates were added when available. Available information that related to adult migration timing (such as jaw tags, radio telemetry, pit tags, freeze brands) was summarized. These timing charts also addressed incubation, rearing, and emergence times.

3. Disease Status and Tolerance

Diseases with management importance, as **defined** by the Model Comprehensive Fish Health Protection Program for the Pacific Northwest (Wold et al. 1987), were listed in the standard table coded "TD". These diseases are generally those that restrict stock transfers. In some cases agencies reported more comprehensive lists. Any known **subbasin** specific information on resistance or treatment response was cited in the text.

4. Stock Size, Stock Recruitment

Accounting for the number of recruits per spawner **first** requires an estimate of the total number of **spawners**. Age-specific return data for a series of years is then needed to track the recruits. **Standard age** composition table code "RN" reports a breakdown of spawner escapement by total age. Age specific estimates of sport catch (code RS), hatchery rack (code **RH**), and **subbasin** totals (code RB), were also generated when possible.

In the special case of summer steelhead, the total age assigned may have been the eventual total age of the fish at maturity in the spring. Steelhead needing such a projected total age might include steelhead non-lethally sampled in August at a weir or ladder during the first calendar year of their two year run span. These fish would not be spawning until the following spring. Such data was only reported if it was considered an adequate sample for describing the age composition of the run at maturity.

Estimates of the total number of smolts were included in standard table (code JM) that reports outmigration totals by season and brood year.

5. Freshwater and Ocean Migration Characteristics

Residualism was described in tables of age composition (code AC) that included freshwater age. Anything known about non-anadromous populations existing in sympatry with anadromous forms was discussed in the text.

Ocean and river distribution data are, with few exceptions, only available from coded wire tags recovered during fisheries not designed to scientifically sample distribution. This report focused on providing a **subbasin** specific guide to the available coded wire tag groups, including their number and size at release (table code TR). Numerous reports available from the Pacific States Marine Fisheries Commission and the Pacific **Salmon** Commission detail aspects of time and place of recovery for any coded wire tag code of interest.

6. Survival and Fecundity

Actual measurements of survival by life stage are extremely rare and most **subbasin** specific data are described in a text format.

Fecundity data are also rare, and infrequently measured even in hatcheries. When such data was available, it was reported in standard table "**AF**." Fecundity data are usually a measure of total egg take divided by the number of females spawned. Sometimes the total egg take figure itself is based on old fecundity estimates multiplied by the number of females.

The proportion of females in a brood's various age classes are reported in a table coded "AS". The "Total % Female" value in this table is based on the age composition of a brood, weighted by the "% Female" in each age class (unless otherwise stated). For example, if 10% of a **coho** brood returned at two years of age, the rest as three year olds, all of the jacks were male, and fifty percent of the adults were female, then:

$$(.10 \times .00) + (.90 \times .50) = .45$$

Forty-five percent of the accounted for brood was female.

The "N" reported in this table is the sum of the fish belonging to the brood that were actually aged and sexed.

7. Age and Size Composition, Life Stage Timing

The timing of early life stages was reported in charts developed for the **Subbasin** Production Plans. These charts (coded **TT**) depict the freshwater life history of the **salmon** and steelhead.

Length was the most **universally** measured parameter of smolt size. Mean length, range, and sample size basis were displayed for outmigrating smolts (table code SL). Such data may reflect rearing conditions or the timing of outmigration sampling, therefore a reference was included directly in these tables.

The life history **trait** of freshwater/ocean age combinations was displayed in standard table "AC". In this and other tables, the number of years of freshwater residence is denoted by the number displayed before a decimal point. The balance of the total age in years (usually equivalent to the number of years of saltwater residence) follows the decimal point. Thus a **coho** jack salmon would be described as a "2.0", a three year adult a "2.1".

The "N" column in the table reports the sum of fish belonging to a brood that were aged. This was a crude measure of confidence, because each of the run years summed could have had a different sampling rate. Note the size of entire brood was reported elsewhere.

Adult length data was displayed utilizing the above freshwater-ocean age specific format. Methods, sample size and standard deviations are also included in standard table code "AL". Because the **availability** of weight data is rare, no standard tables were developed to report this data.

8. Current Rearing and Release Methods (Hatcheries)

Standard table code "TR", based on a Washington Department of Fisheries format reports most of the information concerning hatchery releases. The use of a uniform set of definitions for the 'Life Stage' at release column proved impossible, both between, and within some states. The states therefore defined the terms they used for this table.

Outplanting was described in the hatchery release table. The reporting of all hatchery releases in the Columbia **Basin** in a common format, on 8.5 x 11 inch paper led to less detail than is available in the assorted source databases. Further CIS development will likely allow additional detail for this table. For instance in the 'Release Site' field, where presently **only** the common name of the creek or river of release is listed.

9. Anatomical and Biochemical Traits

A collection of electrophoretic tables from major published works in the Columbia Basin were collected and appear as appendices. These tables were reproduced verbatim, and reflect the nomenclature used by researchers to report allele frequencies at their time of publishing. Efforts have subsequently been made by the American Fisheries Society to standardize the reporting of this type of information. The availability of meristic data was noted for the applicable subbasins.

10. Genetic Variability, Straying

Emigration and **immigration** were described in a standard table format proposed by Idaho (standard

table codes **AE** and **AI**). These tables report the number of carcasses examined for coded wire tags at hatcheries and during spawning ground surveys, the number of tags recovered, and an expanded “total number estimated” based on the numbers reported by PSMFC. Approximately 4,600 individual coded wire tag codes have been released to date in the Columbia River Basin, the bulk of these into Washington and Oregon waters. Harvest recoveries were not listed in the standard form of the these tables.

Standard, and Non-standard Table Codes.

A collection of standardized tables conveyed the above information. An upper case, two letter code identifies the category of these tables. The standard table codes are as follows:

- (HB)** NPPC habitat quality
- (RN)** Returns back as Natural spawners.
- (RH)** Returns back to a Hatchery. 99% of the time these are **rack** returns, but a few places with 100% marking have made splits between marked and unmarked fish.
- (RT)** Tribal catch in the **subbasin**
- (RS)** Sport catch in the subbasin.
- (RB)** **Subbasin grand** total, (subbasin catches, natural and hatchery escapement).
- (JM)** Number of juvenile migrants
- (SL)** Length of smolts
- (AC)** Age composition (freshwaterocean)
- (AS)** Percent females by brood year and age class
- (AL)** Mean fork length by brood year and age class
- (AF)** Mean fecundity by brood year and age class
- (TR)** Hatchery releases by brood year
- (AE)** Emigration of tagged fish
- (AI)** Immigration of tagged fish
- (TD)** Parasites and diseases
- (AD)** Distribution, present/potential and absence figure
- (TT)** **Subbasin** plan bar chart of life stage timing

Deviations from the standard formats, (i.e. run years instead of brood years), are identified with a third lowercase letter such as: RS-a or RS-b.

Tables for categories of information without standardized formats also have a third lowercase letter, and were coded as follows:

- | | |
|------------|--|
| TS-a, etc. | Survival tables, any life stage |
| ST-a, etc. | Non-standard Smolt Timing information |
| AT-a, etc. | Non-standard Adult Timing information |
| AH-a, etc. | Adult Harvest information, i.e. Ocean or mainstem |
| ET-a, etc. | Egg Take data |
| AW-a, etc. | Mean weight by brood year and age class |
| JC-a, etc. | Juvenile age Composition |

RESULTS

The results of this project are contained in five volumes.

Volume I includes the following Oregon subbasins below Bonneville Dam:

Lower Columbia
Mid-Willamette
Clackamas
Molalla
Tualatin
Coast Range
Santiam
Mckenzie
Coast Fork
Long Tom
Middle Fork
Sandy
Hood River

Volume III includes the following Washington subbasins below McNary Dam:

Lower Columbia
Grays
Elochoman
cowlitz
Kalama
Lewis
Washogal
Wind
White Salmon
Klickitat

Volume V includes the following Idaho subbasins:

Cleatwater
Mainstem
South Fork
Mid Fork
Locksa
Selway

Volume II includes the following Oregon subbasins above Bonneville Dam:

15 Mile
Deschutes
John Day
Umatilla
Grande Roncle (including data for Washington)
Imnaha

Volume IV includes the following Washington subbasins above McNary Dam:

Walla Walla (including data for Oregon)
Snake
Tucannon
Yakima
Upper Columbia
Wenatchee
Entiat
Wells
Methow
Okanoagan

Salmon River
Lower **Mainstem**
Little **Salmon**
Mid-Mainstem
Upper **Mainstem**
Lemhi
Headwaters
South Fork
Pahsimeroi

The following Tables 1 through 6 summarize, by species, the presence or absence of the standardized (and some **non-standardized**) tabular data for the Washington subbasins below McNary Dam. Tables 7 through 12 cover the region above McNary Dam.

LOWER COLUMBIA SUBBASIN

Chum Salmon

GEOGRAPHIC LOCATION

The Lower Columbia River **Subbasin** encompasses the Columbia River from its mouth to Bonneville Dam at RM 146, including tributaries that are not covered by individual subbasins of their own. Tributaries not covered in other subbasins that historically contributed significantly to the total production of chum from the Columbia River include the Chinook and Deep Rivers, Crooked, Jim Crow, Skamokawa, **Mill**, Abernathy, Germany, Coal, Salmon, Duncan, Hardy and Hamilton creeks.

The Chinook River enters the Columbia River at River Mile (**RM**) 4, three miles east of the town of Chinook. Deep River enters the Columbia at RM 20 on Grays Bay. Smaller tributaries that enter the Columbia and supported chum runs include Crooked Creek (**RM** 21 one **mile** east of the Grays River), and Jim Crow Creek (**RM** 29 at the town of Brookfield, Washington). The headwaters of both Crooked and Jim Crow Creeks originate on Elk Mountain. Skamokawa Creek enters the Columbia at RM 33, Mill Creek at RM 54 just east of Oak Point, Abernathy Creek at RM 54, Germany Creek at RM 56 near the town of Stella, **Coal** Creek at RM 60, Salmon Creek at RM 87 about 10 miles west of Vancouver, Hardy and Hamilton creeks both at RM 142. A former production area in lower Duncan Creek was reduced to minor importance by a dam built in 1964 (**WDF**, 1973). Tributaries lumped into this **subbasin** vary widely in size and character. Most of these streams are relatively short in length with Jim Crow the shortest at 5 miles and Salmon Creek the longest at 26 miles in length. Most of these areas except Hardy and Hamilton Creeks have only small runs, if any, at present (**WDF**, 1973).

Sea Resources and the Abernathy Hatchery have both developed runs of chum. Sea Resources Hatchery is located on the Chinook River.

ORIGIN

Chum are native to the lower Columbia River tributaries. However, due to low numbers of native chum, Hood Canal and Willapa Bay stocks have been used for supplementation including fry releases from egg boxes on Abernathy, Germany, and Skamokawa Creeks and eyed egg plants into Hamilton Springs, a tributary of Hamilton Creek (Allen, 1983). Hood Canal stock eggs were used because native Columbia River stock eggs were hard to find in significant numbers. Based on subsequent spawning ground surveys, success of these programs seems to be minor. Howell et al. (1985) report a run of chum developed from Willapa Bay stock (**Nemah** River) at the private Sea Resources Hatchery. The first chum egg collection at Chinook River was in 1918 (**WDF**, 1951). Sea Resources Hatchery began operation in 1895. The 1986 brood egg box program at Abernathy Hatchery utilized Willapa Bay chum (**Fiscus**, 1991).

DISTRIBUTION

Chum salmon are found in the lower sections of tributaries flowing into the Columbia River below Bonneville Dam. Primary wild production areas where annual stream surveys are conducted include the Grays River **subbasin** and Hardy and Hamilton Creeks.

PRODUCTION

Chum runs throughout the Columbia River drainage have declined drastically from their former abundance. Washington Department of Fisheries estimated escapement of chum in some lower Columbia River tributaries in 1951. Those estimates include Abernathy (300), Coal (400), Mill and Germany (both 1,000), Crooked and Jim Crow (1,200), Skamokawa (3,000) and Salmon Creek to Bonneville (4,000). Today the composite Columbia River run is reduced to less than 0.5 percent of historic levels with returns averaging in the neighborhood of 2,000 fish (NPPC, 1986). Habitat degradation caused by forest and agricultural practices, urbanization and pollution, along with heavy fishing mortality contributed to the decline (WDF, 1990). The outlook for Columbia River chum is not good (Chaney and Perry, 1976) since the runs have not responded to reduced fishing exploitation (Fulton, 1970).

The number of chum spawning annually in the area near Bonneville Dam, chiefly in Hardy and Hamilton Creeks, averaged about 1,000 fish from 1967 - 1971 (WDF, 1973). Hardy Creek chum natural spawn escapement from 1979 - 1985 brood years averaged 205 ranging from a low of 10 for the 1979 brood to a peak of 802 for the 1984 brood. Hardy Creek chum natural spawn escapements by age and brood year are listed in Table 1.

Hamilton Creek natural spawn escapement from 1979 - 1985 brood years averaged 111 ranging from a low of 15 for the 1979 brood and a peak of 359 for the 1982 brood. Hamilton Creek chum natural spawn escapements by age and brood year are listed in Table 2.

Sea Resources Hatchery chum returns from 1986 - 1990 return years were 74, 92, 345, 247, and 1,055 fish, respectively. However, Sea Resources chum returns by age and brood year are unavailable.

Abernathy Hatchery chum returns in 1990 were 142 fish. In addition, an estimated 100 fish spawned naturally in Abernathy Creek in 1990. Two complete surveys were made in 1990 to document the natural spawning from 1986 brood Willapa Bay stock chum released from the Abernathy egg box program. The 1990 natural spawn counts were well above the recent years background levels. These levels for 9 of the 10 years between 1980 and 1989, averaged less than one chum during single spawning ground surveys on the lowermost 0.4 miles of Abernathy Creek (Fiscus, 1991).

No sport harvest of chum occurs in the smaller Lower Columbia River tributaries.

ADULT LIFE HISTORY

Run size, catch and escapement

Chum salmon are not generally harvested in the ocean commercial and recreational fisheries. A few fish have been caught off of central Alaska (Johnson et al. 1976).

Maximum historical chum landings for the Columbia River have been estimated as high as 697,000 fish in 1928 (Northwest Power Planning Council, 1986). In 1942, landings were 425,000 fish but by 1955 they had diminished to 10,000 fish. Since 1965, commercial landings have been less than 2,000 fish annually (Columbia Fish Runs and Fisheries, 1988). There is no data with which to determine what portion of these catches were from specific tributaries. Historically chum were harvested in the **mainstem** by a variety of methods. Today chum are harvested in **mainstem** gill net fisheries as incidental catch during late fall seasons targeting on late **coho**. Local biologists familiar

with **the** fisheries and spawning ground assessments in Washington suggest the harvest rate may approximate 35 to 50 percent (**WDF**, 1990). No freshwater recreational harvest occurs in the lower Columbia River tributaries.

Lower Columbia River chum have not been coded wire tagged and there have been no stray tag recoveries in the Lower Columbia River subbasin.

Time of Migration

Adults migrate into the Columbia River from mid-October through November (**WDF**, 1990).

Spawning Period

Peak spawner counts generally occur in mid-December in Hardy and Hamilton Creeks (Howell et al. 1985).

Spawning Areas

Chum salmon are found in the lower sections of tributaries flowing into the Columbia River below Bonneville Dam. Wild production areas where annual stream surveys are conducted include the lower 0.7 miles of Hardy Creek and the lower 1.0 miles of Hamilton Creeks.

Age composition

Chum return as three-year-old to six-year-old adults with three-year-old and four-year-olds usually the dominant age classes. Columbia River chum do not return as two-year-old jacks (Howell et al. 1985). Tables 3 and 4 list the age composition percentages by brood year and **freshwater.ocean** rearing for chum returning to Hardy and Hamilton Creek spawning grounds, respectively.

Sex ratio

Females comprised 47 - 67 percent of the chum returning to Hardy Creek spawning grounds between 1979 - 1985 brood years. The percent females by brood year and **freshwater.ocean** rearing ages for Hardy Creek natural spawners are presented in Table 5.

Females comprised 27 - 67 percent of the chum returning to Hamilton Creek spawning grounds between 1979 - 1985 brood years. The percent females by brood year and freshwater-ocean rearing ages for Hamilton Creek natural spawners are presented in Table 6.

The mean fork length by brood year, sex, and freshwater-ocean rearing ages of Hardy and Hamilton Creek natural spawners for 1977 - 1987 brood years are available in Tables 7 and 8.

Fecundity

Fecundity averaged 2,241 eggs per female at Sea Resources Hatchery on the Chinook River between 1984 - 1987 (Howell et al. 1985). Other fecundity data is not available.

JUVENILE LIFE HISTORY

Time of Emergence

Time of emergence is estimated to be early spring; mid March to early April.

Time, age and size at migration

Juvenile chum migrate to sea as zero-age smolts (Hart, 1973). Skamokawa Creek 1978 brood chum averaged 38 mm and ranged from 36 - 40 mm. Table 9 lists the lengths of juvenile chum from stick seining Skamokawa Creek between March 16 - May 18, 1979. Length data of other natural chum smolts is unavailable. The number of natural juvenile chum salmon that migrate from the Lower Columbia River tributaries is also unavailable. Hatchery release information is available in Table 10.

Survival Rate

Survival rate information is unavailable.

BIOCHEMICAL-GENETIC CHARACTERISTICS

Data has not been compiled.

DISEASE

Bacteria and parasitic diseases found in the Lower Columbia River tributaries are unavailable.

Location and year	No. Fish	Length ave. (mm)	Length range (mm)	Reference
Standard and McDonald Creek to mouth, 1979	10	38.0	36-40	“Spring seining of 1978 brood wild fall chinook juveniles on the Kalama River, Grays River, and Skamakawa Creek. WDF memorandum from Nancy Bluestein to Don McIsaac , December 11, 1979.

Six stick seining trips were made on **Skamokawa** Creek between March ~~16~~-May 18, 1979. Though the seining trips were primarily to evaluate fall chinook natural production, chum were also enumerated and a subsample was measured. Average length and range may reflect rearing and/or outmigration size patterns.

LOWER COLUMBIA RIVER

Naturally Produced Winter Steelhead

GEOGRAPHIC LOCATION

The Lower Columbia River forms the border between Oregon and Washington and although the drainage of this **subbasin** includes tributaries within both Oregon and Washington, this report will focus only on Lower Columbia tributaries within Washington. The Lower Columbia is defined as the Columbia River from its mouth to the Bonneville Dam at river mile (RM) 146. Combined in this report are many tributaries not covered by their own individual **subbasin** report including: Coal Creek (RM 56.4, drainage of 26.9 Square miles), Abernathy Creek (RM 54.3, drainage of 28.7 square miles), Germany Creek (RM 56.2, drainage of 22.5 square miles), Mill Creek (RM 53.9, drainage of 29.1 square miles), Skamokawa Creek (RM 33.3, drainage of 50.6 square miles), and Hamilton and Salmon creeks. Each of these tributaries is generally small in terms of length and drainage area although they each differ widely in size and character. The lower reaches of these tributaries are usually tidally influenced **with** most emptying into broad sloughs. This tidal action can be detected throughout the entire length of the Lower Columbia due to its flat gradient.

ORIGIN

Most of the tributaries of the Lower Columbia River have a natural stock, although one or more of the Chambers Creek, Cowlitz and Beaver Creek hatchery-stocks have been introduced into most of the tributaries so some genetic influence has probably been exerted on the wild stocks.

DISTRIBUTION

Table 1 lists spawning and rearing habitat, by quality, for Lower Columbia River steelhead based on estimates from the Northwest Power Planning Council.

Winter steelhead are distributed throughout the tributaries of the Lower Columbia Subbasin. Distribution on many streams is concentrated in the lower reaches.

PRODUCTION

Production Facilities

No steelhead hatcheries exist on any of the streams covered by this report. Steelhead hatcheries which operate on major tributaries to the Lower Columbia and release fish into this **subbasin** would include the Skamania Hatchery on the Washougal River, Beaver Creek Hatchery on the Elochoman River, and the Cowlitz Hatchery on the Cowlitz River, all of which are covered in other **subbasin** reports.

Production Summary

No data are available on wild smolt production although winter steelhead production is considered low. The **subbasin** covers a large geographic area and most of the lands contained within the **subbasin** have been used for forestry, agriculture and urban development which have all impacted production within **subbasin** streams.

Problems which have both eliminated anadromous fish in some streams and reduced production in others would include the indiscriminate logging, destruction of riparian habitat by agricultural and urban development, and non-point source pollution from agricultural and industrial development

(Subbasin Plan 1990).

ADULT LIFE HISTORY

Run Size and Escapement

No data are available on lower Columbia steelhead.

Time of migration

Wild winter steelhead migration is generally from January through May, peaking in March although migration varies on each individual stream. Figure 1 illustrates a generalized freshwater life history for winter steelhead.

Harvest

Ocean catch of Lower Columbia River winter steelhead are unknown.

Sport harvest on the Lower Columbia will be divided into two categories: 1) sport catch within the **mainstem** Lower Columbia and, 2) sport catch within individual tributaries of the subbasin.

1) Sport harvest on the **mainstem** Lower Columbia River accounts for a large number of steelhead caught (winter and summer) although the vast majority are not from the Lower Columbia **Subbasin** but are fish migrating upstream to other subbasins. Based on WDW permit-card harvest estimates, harvest of winter **steelhead** in the **mainstem** lower river **from** 1980 through 1990 ranged from 423 steelhead in 1983-1984 to 1,473 fish in 1980-1981 (Table 2). Harvest of summer steelhead within the **mainstem** Lower Columbia for the same ten year period ranged from 751 **steelhead** in 1980-1981 to 4,683 fish in 1988-1989 (Table 3).

2) Based on permit-card harvest estimates, sport catch of winter steelhead for all **subbasin** tributaries combined, averaged 453 fish annually from 1977 through 1986. Annual average sport catch within individual **subbasin** streams ranged from a low catch of 2 steelhead from the Chinook River to a high of 196 **fish** from Germany Creek (Table 4).

There are no Indian fishing rights exercised in the small tributaries of this subbasin.

Spawning Period

Spawning is believed to occur from March through June with some variation among the individual tributaries.

Spawning area

Wild winter steelhead are known to spawn in the following areas: **Mainstem** Skamokawa Creek and its tributaries, Mill Creek including the lower section of Little Mill Creek, **mainstem** Abernathy Creek and its tributaries, throughout Germany Creek and, the lower reaches of Coal Creek.

Fecundity

No data are available for steelhead.

Age Composition

No data are available for steelhead.

Size

No data are available for steelhead.

Sex ratio

No data are available for steelhead.

Survival rate

No data are available for **steelhead**.

JUVENILE LIFE HISTORY

Egg

No data are available on egg production or egg to smolt survival.

Emergence

No data are available for steelhead.

Juvenile rearing

Juvenile rearing lasts approximately two years prior to ocean emigration. Juvenile steelhead outmigration generally occurs from April through May at an average size of 160 mm.

Hatchery Releases

The streams and creeks of the Lower Columbia **Subbasin** has received hatchery smolts from the Skamania, Beaver Creek, Chambers Creek and Cowlitz hatcheries. Hatchery releases within individual streams is outlined in Tables 4-1 1.

Straying

No data are available for steelhead.

BIOCHEMICAL-GENETIC CHARACTERISTICS

No data are available for steelhead.

DISEASES

Disease history for smolts planted in the Lower Columbia **Subbasin** is presented in Table 12.

Figure 1 (TT). Generalized freshwater life history of winter steelhead.

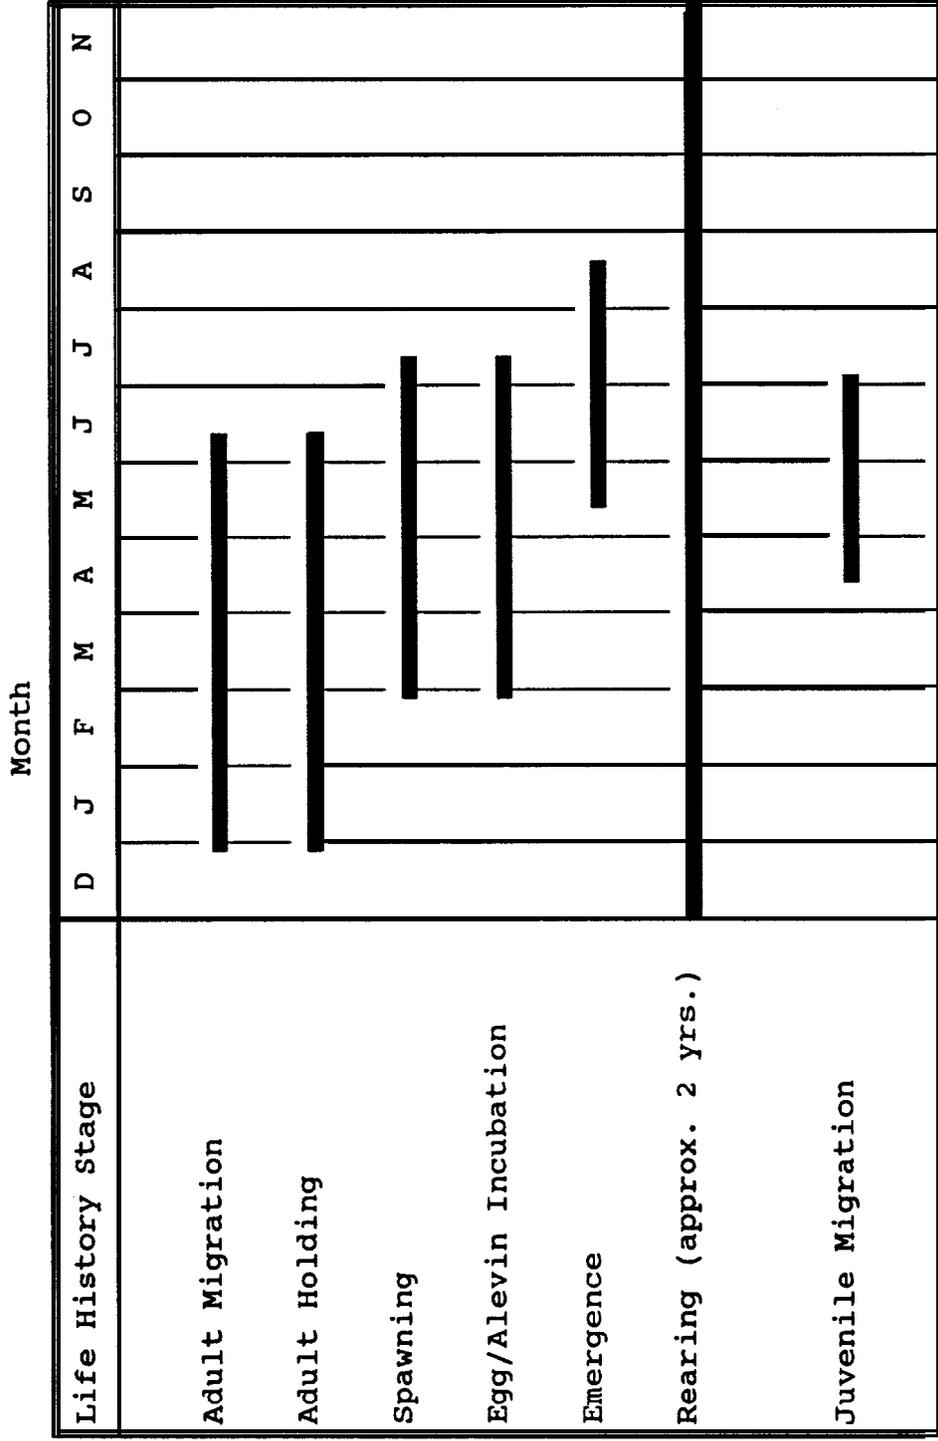

Table 1 (HB-1). Estimated* amount of rearing and spawning habitat, by quality, of Lower Columbia **Subbasin** winter steelhead.

Area	Excellent	Good	Fair ^B	Poor ^B	Unknown	Total	Confidence
Miles	14.2%	40.9%	37.0%	7.9%		240.3	Unknown
Acres	13.7%	48.0%	32.7%	5.7%		336.5	Unknown

*Northwest Power Planning Council estimates based on limited observations.

^B**Ratings** of fair and poor may reflect natural physical features such as waterfall barriers, as well as degradation caused by humans.

Table 2 (RS-a). Returns (sport catch/escapement) of winter steelhead to the Lower Columbia Subbasin.

Return Year	Sport Catch ^{A B C}	Escapement	Adult Total
1980-81	1527	No data	Unknown
1981-82	1711	No data	Unknown
1982-83	1135	No data	Unknown
1983-84	677	No data	Unknown
1984-85	913	No data	Unknown
1985-86	718	No data	Unknown
1986-87	1202	No data	Unknown
1987-88	1148	No data	Unknown
1988-89	775	No data	Unknown
1989-90	1104	No data	Unknown

^A**Sport** catch includes **mainstem** Lower Columbia and its tributaries.

^B**Sport** catch on **mainstem** river comprised mainly of steelhead migrating to other subbasins.

^C**Sport** catch only within tributaries of the Lower Columbia presented in Table 4.

Source: Sport Catch, Washington Department of Wildlife permit-cards.

Sport catch includes: Main Stem Lower Columbia, Germany Creek, Coal Creek, Abernathy Creek, Salmon Creek, **Skamokawa** Creek.

Table 3 (RS-b). Sport catch of summer steelhead in the **mainstem** Lower Columbia River.

Return Year	Sport Catch [^]
1980	751
1981	1,225
1982	2,090
1983	1,694
1984	1,624
1985	2,728
1986	2,965
1987	4,821
1988	2,612
1989	4,683
1990	3,894

[^]**Summer** steelhead are not indigenous to this **subbasin** although some summer fish were introduced into the subbasin, no further planting occurs and it is assumed very little if any natural production occurs, thus the summer steelhead sport catch is from fish migrating upstream to other subbasins.

Source: Sport catch from permit-card harvest estimates.

GRAYS SUBBASIN

Fall Chinook

GEOGRAPHIC LOCATION

The Grays River originates in the southeast Pacific County and flows southwest through Wahkiakum County to its confluence with the Columbia River at River Mile **(RM)** 21. The lower six miles of the river are a slough subject to tidal influence. The next six miles flow through a wide, flat valley before entering the steep foothills. Most of the upper watershed flows through steep narrow canyons in the rugged Willapa Hills. The entire basin encompasses 124 square miles. Grays River Salmon Hatchery is located on the West Fork of the Grays.

ORIGIN

A native population of fall chinook was in existence on the Grays River prior to construction of the Grays River Salmon Hatchery in 1960. Mixing of stocks very likely began to occur **when** hatchery supplementation was initiated in 1947 with the release of 100,090 tule fall **chinook** fingerlings **(WDF, 1990)**. This supplementation and hatchery brood stock were a mix of local stock and transfers from other hatcheries, primarily Spring Creek Hatchery. Brood stock for the Grays Hatchery are collected at a rack and the remaining adults are passed upstream to spawn naturally. In recent years, broodstock for Grays River Hatchery also has been collected from Grays River spawning grounds and at other lower river spawning grounds and hatcheries. It is presumed there are no differences between hatchery stock and naturally spawning populations, as no effort was, nor is, being made to keep them separate.

DISTRIBUTION

Grays River **mainstem** natural production extends from the head of tidewater upstream to above the West Fork. Some spawning also occurs in the West Fork Grays River below the hatchery rack.

PRODUCTION

Hatchery production is the dominant component in the Grays River although some natural production also occurs.

Tables 1 and 2 describe the amount of spawning and rearing habitat by quality, available in the Grays River. This data was derived from the Presence/Absence database of Northwest Power Planning Council, 1991.

The Grays River fall chinook natural spawn escapement from 1978 - 1984 brood years averaged 869 with a low return of 411 for the 1978 brood and a peak of 2,079 for the 1984 brood. Natural spawn escapements by age and brood year are presented in Table 3.

Grays River Hatchery fall chinook returns from 1976 - 1984 brood years averaged 619 with a low return of 45 for the 1977 brood and a peak of 2,080 for the 1984 brood. Hatchery returns by age and brood year are presented in Table 4.

Grays River tributary sport catch estimates between 1981 - 1988 return years averaged 156 adult fall chinook, ranging from a low of 17 in 1983 to a high of 342 in 1987 based on punchcard and limited actual sampling data. However, specific age and brood year analysis for Grays River sport catch is

unavailable.

ADULT LIFE HISTORY

Run size, catch and escapement

Ocean commercial and recreational fisheries from Alaska to Washington, in addition to Columbia River gill net and sport fisheries all harvest a portion of the Grays River origin fall chinook. Columbia River sport and commercial fisheries are managed to ensure attainment of hatchery **egg-take** requirements.

Strays from other lower river hatcheries are not unusual. Table 5 lists Grays Hatchery origin fall chinook stray coded wire tag recoveries beginning with the 1978 brood through to the 1988 brood, and Table 6 lists the coded wire tags recovered within the Grays **subbasin** which originated outside the Grays subbasin.

Time of Migration

Upstream migration begins from early August to early September depending partly on early fall rains.

Spawning Period

Natural spawning occurs between late September and mid-November, usually peaking in **mid-October**.

Spawning Areas

Grays River **mainstem** natural production extends from the head of tidewater upstream to above the West Fork. Some spawning also takes place in the West Fork Grays River below the hatchery rack.

Age Composition

Age ranges from two-year-old jacks to six-year-old adults with three-year-olds or four-year-olds usually the dominant age class. Total age composition data is summarized in Tables 3 and 4. Table 7 lists the age composition percentages by brood year and **freshwater.ocean** rearing for fall chinook returning to the Grays River spawning grounds. Table 8 lists the age composition percentages by brood year and **freshwater.ocean** rearing for fall chinook returning to the Grays River Hatchery.

Ratio

Female fall chinook comprised 36 - 63 percent of the natural spawners in the Grays River between 1981 - 1984 brood years. The percent females by brood year and **freshwater.ocean** rearing ages for Grays River natural spawners are presented in Table 9.

Female fall chinook comprised 31 - 43 percent of the fall chinook returning to the Grays Hatchery between 1981 - 1984 brood years. The percent females by brood year and **freshwater.ocean** rearing ages for Grays Hatchery returns are presented in Table 10.

The mean fork length by brood year, sex, and freshwater-ocean rearing ages of Grays River natural

spawners for 1979 - 1983 brood years are available in Tables 11 and 12. The mean fork length by brood year, sex, and freshwater-ocean rearing ages for Grays Hatchery returns from 1978 - 1984 brood years are available in Tables 13 and 14.

Fecundity

Fecundity at the Grays Hatchery between 1983 - 1990 return years averaged 4,312 and ranged from a low of 4,148 in 1983 to a high of 4,720 in 1990. Grays River natural spawn and Grays Hatchery fecundity data by age and brood year is unavailable.

JUVENILE LIFE HISTORY

Time of Emergence

Emergence times were estimated to be early April for naturally spawning fry, depending on time of egg deposition and water temperatures (Howell et. al., 1985).

Time, age and size at migration

Hatchery release information for the Grays **subbasin** by brood year is presented in Table 15. Length data of 1978 brood natural fall chinook smolts from the Grays River is available in Table 16. The number of natural juvenile fall chinook salmon that migrate from the Grays River is unavailable.

Survival Rate

Data not available.

BIOCHEMICAL-GENETIC CHARACTERISTICS

Schreck et al. (1986) determined from electrophoresis that Bonneville Hatchery fall chinook and **Spring Creek Hatchery (BPH)** had 11 similar isozyme gene **frequencies** and none dissimilar. They **did not**, however, **analyze** fall chinook from the **Grays Hatchery**.

DISEASE

Bacteria and parasitic diseases found in the Grays Hatchery are listed in Table 16. (WDF Salmon Culture, Olympia)

Table 1 (**HB-1**). Estimated amount of rearing and spawning habitat, by **quality**, of the Grays River fall chinook production area.

Distance/Area	Excellent	Good	Fair ^a	Poor ^a	Unknown	Total	Confidence
Miles (%)	31	69	00	00		31.9	
Acres (%)	27	73	00	00		117.2	

“Ratings of fair and poor habitat quality may reflect natural physical **features** such as waterfall barriers, as well as degradation caused by humans.

Source: Presence/Absence database, NPPC, 1991.

Table 2 (**HB-2**). Estimated amount of rearing habitat, by quality, of the Grays River fall chinook production area.

Distance/Area	Excellent	Good	Fair ^a	Poor ^a	Unknown	Total	Confidence
Miles (%)	100	00	00	00		6.5	
Acres (%)	100	00	00	00		11.8	

“Ratings of fair and poor habitat quality may reflect natural physical features such as waterfall barriers, as well as degradation caused by humans.

GRAYS SUBBASIN

Coho

GEOGRAPHIC LOCATION

The Grays River originates in the southeast Pacific County and flows southwest through Wahkiakum County to its confluence with the Columbia River at River Mile (RM) 21. The lower six miles of the river are a slough subject to tidal influence. The next six miles flow through a wide, flat valley before entering the steep foothills. Most of the upper watershed flows through steep narrow canyons in the rugged Willapa Hills. The entire basin encompasses 124 square miles.

A number of tributaries of the Grays River have good to excellent **coho** production potential. Among these are Hull, Fossil, and Mitchell Creeks, and the East, North, and South Forks of the Grays River (WDF, 1973).

Grays River Hatchery is located 2.5 miles upstream from State Highway 4 on the West, Fork of the Grays River. The hatchery is 21 miles from the mouth of the Columbia River. Grays River Hatchery is the sixth hatchery constructed under the Columbia River Fisheries Development Program and began operation in 1961.

ORIGIN

Washington Department of Fisheries (1951) reported Grays River had native late (Type-N) stocks. The current hatchery program produces early (Type-S) **coho**. Most existing early (Type-S) **coho** hatchery programs are considered linked, in varying degrees, to native Toutle River stock **coho**. These fish provided the basis for the who rearing program, beginning in 1952, at the Toutle Hatchery on the Green River. The hatchery program was very successful and, consequently, surplus eggs were readily available for transfer to other stations. Because of extensive transferring of eggs between most Columbia River facilities, releases considered to be of Toutle River ancestry are probably a mixture of various early **coho** production (Howell et al. 1985).

DISTRIBUTION

Natural spawning occurs in most areas accessible to **coho**.

PRODUCTION

U.S. Fish and Wildlife Service surveys in 1936 and 1937 indicated **coho** were present in all accessible tributaries of the Grays River, but no population estimates were made. Portions of the watershed were being logged, and splash dams, log and debris jams, and logging through the streams had probably already adversely affected fish production. Under the Columbia River Fisheries Development Program some of these problems were addressed on an ad hoc basis and production was extended by removing natural and man-made barriers. In 1951, Washington Department of Fisheries estimated **coho** escapement at 2,500 fish.

Tables 1 and 2 describe the amount of spawning and rearing habitat, by quality, available in the Grays River. This data was derived from the Presence/Absence database of the Northwest Power Planning Council, 1991.

Subbasin natural production potential was estimated to be 125,874 smolts using the Smolt Density Model. Natural spawning is presumed of early stock **coho**, through anecdotal information, to be quite low and subsequent juvenile production well below stream potential. Some natural production of late stock **coho** exists but probably does not exceed 10 - 15 percent (Howell et al. 1985).

Current production of **coho** at the Grays River Salmon Hatchery is limited by the need to rear fish for the Toutle River program, whose hatchery was destroyed in the Mount St. Helens eruption.

The number of Grays River **coho** natural spawn escapement is unavailable. Grays River Hatchery **coho** returns from 1978 - 1988 brood years averaged 2,684 with a low return of 468 for the 1984 brood and a peak of 5,382 for the 1979 brood. Grays River Hatchery returns by-brood year and age class are presented in Table 3.

Grays River tributary sport catch estimates between 1981 - 1988 return years averaged 68 adult **coho**, ranging from a low of 4 in 1981 and a high of 177 in 1984 based on catch records and limited actual sampling data. However, specific age and brood year analysis for Grays River sport catch is unavailable.

ADULT LIFE HISTORY

Run size, catch and escapement

Ocean commercial and recreational fisheries off the Oregon coast are the primary harvesters of early **coho**. The Oregon troll fishery accounts for the highest percentage of the overall catch. Early **coho** are distributed to coastal Oregon fisheries more heavily than their more northerly distributed late cohorts. Based on coded-wire tagged releases of 1976 - 1978 brood late **coho**, most of the harvest occurs in the Washington and Oregon ocean fisheries. This reflects the catch distribution where the Washington coastal late **coho** catch comprised 40 percent of the total harvest compared to 20 percent for early **coho** during 1979 - 1981. Late **coho** also contribute significantly to the lower Columbia River commercial gill net fishery. Harvest rates have averaged 79 percent and 85 percent for early and late **coho** stocks, respectively, between 1983 and 1987. Columbia River harvest of early **coho** is occasionally constrained by one or more of the fall chinook stocks. Harvest of late **coho** is generally not constrained by weak stocks, with hatchery escapement being the only management constraint (WDF, 1990). Most of the freshwater recreational harvest occurs in the Washington tributaries (Howell et al. 1985).

Strays from other lower river hatcheries are not unusual. Table 4 lists Grays Hatchery origin **coho** stray coded-wire tag recoveries beginning with the 1978 brood through to the 1988 brood. Table 5 lists the coded-wire tags recovered within the Grays **subbasin** which originated outside the Grays **subbasin**.

Time of Migration

Early **coho** enter the Columbia River by mid-August and begin returning to the lower Columbia hatcheries in early September. In the **mainstem** Columbia River early **coho** predominate from August to mid-September. Stock composition shifts to late **coho** in late September and October. Typically, the late **coho** run begins entering freshwater in mid to late September with mid-October considered the main migratory period in the **mainstem** Columbia River (Howell et al. 1985).

Spawning Period

For early **coho**, both hatchery and natural spawning occurs around late October, while for late **coho** spawning extends from late November through March, with the bulk occurring in December and early January (Howell et al. 1985)

Spawning Areas

Natural spawning occurs in most areas accessible to **coho**.

Age composition

Coho return as two-year-old jacks and three-year-old adults. Table 6 lists the age composition percentages by brood year and age class for **coho** returning to Grays River Hatchery. Age composition percentages by brood year and age class for Grays River natural spawners is unavailable.

Sex Ratio

Females comprised 4 - 51 percent of the **coho** returning to the Grays River Hatchery between 1978 - 1987 brood years. The percent females by brood year and age class for Grays River Hatchery returns are presented in Table 7. The percent females by brood year and age class for Grays River natural spawners are unavailable.

Early stock **coho** fork length measurements generally range from 30 - 45 cm. for jacks (Washington hatchery sampling) and 55 - 70 cm. for adults (commercial fishery sampling). Based on sampling of the lower Columbia River commercial fishery during 1980 - 1982, late **coho** adult fork length measurements ranged from about 50 - 70 cm. (Howell et al. 1985). Grays River Hatchery returns and natural spawn escapement mean fork length by brood year and age class are unavailable.

Fecundity

Coho fecundity at the Grays Hatchery for 1977 - 1987 brood years averaged 2,321 and with a low of 1,750 for the 1980 brood and a peak of 2,713 for the 1982 and 1985 broods. Table 8 lists the mean fecundity by brood year and age class for **coho** returning to the Grays River Hatchery. The mean fecundity of Grays River natural spawners brood year and age class is unavailable.

JUVENILE LIFE HISTORY

Time of Emergence

The juvenile life history for Grays River **subbasin coho** is similar to that of other stocks in the region with a spring emergence (WDF, 1990).

Time, age and size at migration

Hatchery information for the Grays River **subbasin** by brood year is presented in Table 9. Length data of natural **coho** smolts from the Grays River is unavailable. The number of natural juvenile **coho** salmon that migrate from the Grays River is also unavailable.

Survival Rate

A generalized recent year smolt-to-adult survival for **coho** was estimated to be 2.5 percent (TAC, 1983).

BIOCHEMICAL-GENETIC CHARACTERISTICS

Data has not been compiled.

DISEASE

Bacteria and parasitic diseases found in the Grays Hatchery are listed in Table 10 (WDF Salmon Culture, Olympia).

Table 1 (HB-1). Estimated amount of rearing and spawning habitat, by quality, of the Grays River **coho** production area.

Distance/Area	Excellent	Good	Fair*	Poor*	Unknown	Total	Confidence
Miles (%)	.27	.68	.06	0.00		48.5	
Acres (%)	.33	.58	.09	0.00		44.8	

*Ratings of fair and poor habitat quality may reflect natural physical features such as waterfall barriers, as well as degradation caused by humans.

Table 2 (HB-2). Estimated amount of rearing habitat, by quality, of the Grays River **coho** production area.

Distance/Area	Excellent	Good	Fair*	Poor*	Unknown	Total	Confidence
Miles (%)	.31	.50	.19	0.00		8	
Acres (%)	.82	.02	.17	0.00		14.1	

*Ratings of fair and poor habitat quality may reflect natural physical features such as waterfall barriers, as well as degradation caused by humans.

Source: Presence/Absence database, NPPC, 199 1.

Table 3 (RH). Total hatchery returns of **coho** to the Grays River Hatchery by brood year.

Total Age

Brood Year	2	3	Total	Adult Total
1978	1,040	530	1,570	530
1979	1,313	4,069	5,382	4,069
1980	1,744	178	1,922	178
1981	112	2,684	2,796	2,684
1982	89	828	917	828
1983	182	1,883	2,065	1,883
1984	92	376	468	376
1985	1,012	3,035	4,047	3,035
1986	1,609	3,739	5,348	3,739
1987	731	1,488	2,219	1,488
1988	1,071			

Age composition based on hatchery personnel designation of adults and jacks. Adult **coho** assumed to be 2.1 and jacks 2.0.

Table 4 (AE). Emigration of coded wire tagged coho from the Grays River subbasin..

Hatchery/Release Site	Recovery site, Run Year(s)	Recovery Method	Number Sampled	Number Recovered	Total Number Estimated, (PSMFC)
Grays River Hatchery	Grays River, 1982	Spawning Ground	36	4	139

Grays River Hatchery	Elochoman, 1988	Hatchery	2,766	1	1
Grays River Hatchery	Cowlitz, 1986	Hatchery	54,685	1	1

*Based on the following tag codes: 63-22-43, 63-42-47, 63-42-50, 63-32-59, 63-32-60, 63-32-61, 63-32-62, 63-32-63, 63-33-01, 63-42-49, 63-42-52, and 63-32-59.

Beginning with the 1978 brood.

Table 5 (AI). Immigration of coded wire tagged coho into the Grays River subbasin.

Hatchery/Release Site	Recovery site, Run Year(s)	Recovery Method	Number Sampled	Number Recovered	Total Number Estimated, (PSMFC)
Grays River Hatchery	Grays River, 1982	Spawning Ground	36	4	139
Willard Hatchery, released Hammond	Grays River, 1981	Hatchery	1,843	1	1
Grays River Hatchery	Grays River, 1988	Spawning Ground	14	1	---

*Based on the following tag codes: 63-22-43, 05-06-53, and 63-42-47. Beginning with the 1978 brood.

Table 6 (AC). Age composition percentage (freshwater.ocean) by brood year for coho returning to the Grays River Hatchery.

Age Composition (%)

Brood Year	N	2.0	2.1
1978		66.24	33.76
1979		24.40	75.60
1980		90.74	9.26
1981		4.01	95.99
1982		9.71	90.29
1983		8.81	91.19
1984		19.66	80.34
1985		25.01	74.99
1986		30.09	69.91
1987		32.94	67.06
1988			

Age composition based on hatchery personnel designation of adults and jacks. Adult coho assumed to be 2.1 and jacks 2.0.

N (Number of scale samples) not applicable.

Table 7 (AS). Percent females by brood year and age class (**freshwater.ocean**) for coho returning to the Grays River Hatchery.

Females (%)

Brood Year	N	2.0	2.1	Total % Female
1978		0	49.06	16.56
1979		0	36.62	27.68
1980		0	40.45	3.75
1981		0	53.09	50.97
1982		0	54.23	48.96
1983		0	39.94	36.42
1984		0	42.29	33.97
1985		0	34.17	25.62
1986		0	43.38	30.33
1987		0	38.31	25.69
1988		0		

Age composition based on hatchery personnel designation of adults and jacks. Adults assumed to be 2.1 and jacks 2.0. Females assumed to be adults.

N (Number of scale samples) not applicable.

Table 8 (AF). Mean fecundity by brood year and age class (freshwater.ocean) for coho returning to the Grays River Hatchery.

Mean Fecundity

Brood Year	2.0	2.1
1977	0	2,623
1978	0	2,258
1979	0	1,933
1980	0	1,750
1981	0	2,600
1982	0	2,713
1983	0	2,516
1984	0	2,547
1985	0	2,713
1986	0	1,818
1987	0	2,537
1988	0	

Age composition based on hatchery personnel designation of adults and jacks. Adults assumed to be 2.1 and jacks 2.0. All females were assumed to be adults.

Table 9 (TR). Hatchery releases of COHO salmon into the GRAYS RIVER subbasin sorted by brood year, hatchery and life stage.

GRAYS SUBBASIN

Chum Salmon

GEOGRAPHIC LOCATION

The Grays River originates in the southeast Pacific County and flows southwest through Wahkiakum County to its confluence with the Columbia River at River Mile (RM) 21. The lower six miles of the river are a slough subject to tidal influence. The next six miles flow through a wide, flat valley before entering steep foothills. Most of the upper watershed flows through steep narrow canyons in the rugged Willapa Hills. The entire basin encompasses 124 square miles.

A number of tributaries of the Grays River area have historically supported chum salmon runs. Among those were Seal, Malone, Hull, Klints, and Fossil Creeks, and the West Fork of the Grays River. Most of these area have only small runs, if any, at present (WDF, 1973).

Grays River Hatchery is located 2.5 miles upstream from State Highway 4 on the West Fork of the Grays River. The hatchery is 21 miles from the mouth of the Columbia River. Grays River Hatchery is the sixth hatchery constructed under the Columbia River Fisheries Development Program and began operation in 1961. Historically the Grays River Hatchery has raised chum though it does not currently.

ORIGIN

Chum are native to the lower Columbia River tributaries including the Grays River system. However, chum runs throughout the Columbia River drainage have declined drastically from their former abundance. Managers have attempted several times to augment natural chum production by releasing fed fry or fry from egg boxes directly into the stream. The **mainstem** and the West Fork Grays River have both been recipients of intermittent releases since 1972. The present low numbers of chum in the Columbia River made it necessary to use stock from outside the area. In 1976 approximately 1.1 million 1975 brood chum fry from Hokkaido, Japan (Mokoto stock) were released into the West Fork Grays River. These releases apparently had little affect on adults returns. Non-Columbia River stock chum salmon released in the Grays River also included Hood Canal stocks (WDF, 1990).

DISTRIBUTION

Spawning ground surveys include the **mainstem** Grays from River Mile (RM) 9.5 to RM 13.0 and West Fork of the Grays including the lower 1.4 miles, and 0.5 miles of Crazy Johnson Creek. Recent stream enhancement work by the Washington Department of Fisheries Department in Gorley Springs at RM 12 has been relatively successful and may increase basin chum production by providing a stable incubation environment (WDF, 1990).

PRODUCTION

The Grays River was once noted for its large runs of chum salmon. In 1936, 6,286 spawning or spawned-out chum were counted below the falls at RM 13, and an additional 1,388 chum were counted in the West Fork of the Grays River (Bryant, 1949). In 1951, the Washington Department of Fisheries estimated 7,500 chum returned to the Grays River. Logging of the watershed and the resulting landslides, erosion and channel changes caused serious damage to salmon spawning habitat. Today the Grays River chum run is a fraction of its historic run size.

The Grays River chum natural spawn escapement from 1977 - 1988 return years is measured as peak fish counts rather than natural spawn escapement estimates. The Grays River chum natural escapement (except Gorley Creek) has not been calculated. Peak **fish** counts for Grays River chum (including Gorley Creek) for 1977 through 1988 averaged 515 fish and ranged from 107 fish in 1980 to a high of 1,370 in 1988 (**WDF**, 1990). Gorley Creek chum natural spawn escapement from 1983 - 1984 brood years were 27 and 720 fish, respectively. Gorley Creek natural spawn escapements by age and brood year are presented in Table 1.

Few chum are harvested in the tributary recreational fishery.

ADULT LIFE HISTORY

Run size, catch and escapement

Chum salmon are not generally harvested in the ocean commercial and recreational fisheries. A few fish have been caught off of central Alaska (Johnson et al. 1976).

Maximum historical chum landings for the Columbia River have been estimated as high as 697,000 fish in 1928 (Northwest Power Planning Council, 1986). In 1942, landings were 425,000 fish but by 1955 they had diminished to 10,000 fish. Since 1965, commercial landings have been less than 2,000 fish annually (Columbia Fish Runs and Fisheries, 1988). It is impossible, however, to determine what portion of these catches might have been of Grays River origin. Historically chum were harvested in the **mainstem** by a variety of methods. Today chum are harvested in **mainstem** gill net fisheries as incidental catch during late fall seasons targeting on late **coho**. Local biologists familiar with the fisheries and spawning ground assessments in Washington suggest the harvest rate may approximate 35 to 50 percent (**WDF**, 1990). Little or no freshwater recreational harvest occurs in the Grays River.

Grays River chum have not been coded wire tagged and there have been no stray tag recoveries within the Grays River subbasin.

Time of Migration

Chum enter the Columbia River in mid October through November (Chaney and Perry, 1976). Adults migrate into the river from mid-October through November with peak spawner abundance occurring in late November (**WDF**, 1990).

Spawning Period

Peak spawner counts generally occur in late November in the Grays River (Howell et al. 1985).

Spawning Areas

Spawning ground surveys include the **mainstem** Grays from RM 9.5 to Rm 13.0 and the lower 1.4 miles of West Forks of the Grays River. Spawning also occurs in Crazy Johnson Creek and Gorley Springs at RM 12. Seasonal low flows sometimes restrict access of chum to preferred off-channel spawning area confining them to less stable **mainstem** reaches. Some **mainstem** reaches where chum spawn are subject to frequent channel shifts and **bedload** deposition or scour, all of which reduce intragravel survival.

Age composition

Chum return as three-year-old to six-year-old adults with three-year-old and four-year-olds normally the dominant age classes. Columbia River chum do not return as two-year-old jacks (Howell et al. 1985). Table 2 lists the age composition percentages by brood year and freshwater-ocean rearing ages for chum returning to the Grays River spawning grounds.

Sex Ratio

Females comprised 42 - 67 percent of the chum returning to the Grays River spawning grounds between 1979 - 1984 brood years. The percent females by brood year and **freshwater.ocean** rearing ages for Grays River natural spawners are presented in Table 3.

The mean fork length by brood year, sex, and **freshwater.ocean** rearing ages of Grays River natural spawners for 1977 - 1987 brood years are available in Tables 4 and 5.

Fecundity

Fecundity data on Grays River chum are not available.

JUVENILE LIFE HISTORY

Time of Emergence

Time of emergence is estimated to be early spring.

Time, age and size at migration

The peak chum catch during seining of juvenile salmon in the Grays River from March 16 to May 18, 1979 occurred on April 5th (Bluestein, 1979). The fry averaged 41 mm and ranged from 35 - 45 mm in length. Table 6 lists the lengths of juvenile chum from the Grays River in 1979. Juvenile chum migrate to sea as zero-age smolts (Hart, 1973). The number of natural juvenile chum salmon that migrate from the Grays River is unavailable. Hatchery release information is available in Table 7.

Survival Rate

Survival rate information is unavailable.

BIOCHEMICAL-GENETIC CHARACTERISTICS

Data has not been compiled.

DISEASE

Bacteria and parasitic diseases found in the Grays River are unavailable.

Table 6 (SL). Lengths of juvenile chum salmon from the Grays River, 1979.

Location and year	No. Fish	Length ave. (mm)	Length range (mm)	Reference
West Fork & Mainstem, 1979	29	41.0	35-45	"Spring seining of 1978 brood wild fall chinook juveniles on the Kalama River, Grays River, and Skamokawa Creek." WDF memorandum from Nancy Bluestein to Don McIsaac . December 11, 1979

Five stick seining trips were made on the Grays River between March 22-April 26, 1979. Though the seining trips were primarily to evaluate fall chinook natural production, chum were also enumerated and a subsample was measured. Average length and range may reflect rearing and/or outmigration size patterns.

GRAYS RIVER SUBBASIN

Naturally Produced Winter Steelhead

GEOGRAPHIC LOCATION

The **Grays River Subbasin** is located in southwest Washington within Pacific County. Originating in the **Willapa Hills** the **river** drops through numerous steep, narrow canyons which comprise the upper watershed before entering a wide flat valley. The last six miles of the river are a slough subject to tidal influence. Dikes have been constructed in this area to protect the residents of this low-lying land. The Grays River joins the Columbia River at river mile (**RM**) 21 and the entire watershed encompasses 124 square miles.

ORIGIN

The wild winter steelhead stock in the Grays River is native, although interbreeding with introduced Cowlitz, Chambers Creek and Elochoman hatchery stocks has probably occurred.

DISTRIBUTION

Table 1 lists rearing and spawning habitat, by quality, for Grays River steelhead based on estimates from the Northwest Power Planning Council. Washington Department of Wildlife planners using the Smolt Density Model, estimate the watershed can produce 45,300 smolts. Figure 1 illustrates the probable spawning areas of wild steelhead in the Grays River (Howell et al. 1985).

Distribution of winter steelhead occurs throughout the **mainstem** river above tidal reaches, and also within the East, South and West Forks. In the mid-1940's there were reports of several hundred steelhead congregating in the pool below Grays River falls. These steelhead were believed to ascend the falls in high water. **Once** they ascended the falls there were numerous obstacles, natural and man-made which blocked fish migration into the upper reaches of the **mainstem** and many tributaries. During the 1950's explosives were used to lower Grays Falls, in addition other barriers above the falls were cleared to improve steelhead access to the river's upper reaches.

PRODUCTION

Production Facilities

The Grays River Salmon Hatchery is located on the West Fork Grays River. Production is primarily fall chinook and **coho** salmon. No steelhead rearing occurs at the Grays River Hatchery.

Production Summary

No data are available on natural smolt production. Natural production continues in both the **mainstem** Grays and the lower sections of most tributaries. Smolt production throughout the drainage is severely reduced from logging related problems in the watershed.

ADULT LIFE HISTORY

Run Size and Escapement

No estimates of wild run size or escapement exist. Steelhead abundance during the 1920's and 1930's was estimated at 2,000 fish annually (**WDW** 1936). This number has declined due to habitat degradation in the Grays River watershed. Currently, local biologists estimate steelhead escapement

to be between **400** and 600 fish annually. Lucas (1992) estimates spawning escapement for 1991 at 716 fish.

Time of migration

Adult time of entry for wild winter steelhead is generally from January through May with peak returns occurring in March and April.

Harvest

Ocean harvest of Grays River steelhead is unknown. The lower Columbia River supports a popular sport fishery with harvest of some Grays River steelhead contributing to the lower Columbia catch.

Sport fishing occurs throughout the Grays River. Based on punchcard returns, the average annual steelhead sport catch (wild and hatchery) from 1980 through 1990 was 533 fish (Table 2). In 1986, wild release regulations were imposed on the Grays River limiting legal harvest to hatchery fish only. To promote maximum returns on wild fish while providing sport fishing opportunity the state currently emphasizes separation of hatchery and wild stocks. The use of early returning Beaver Creek fish were chosen as the hatchery stock for release into the Grays River thus creating a early returning hatchery stock with a later returning native stock.

Indian fishing rights are not exercised on the Grays River.

Spawning period

Wild steelhead spawning occurs from March through mid-June.

Spawning area

Wild steelhead spawn throughout the Grays River, and in the lower reaches of the East, South and West forks and in other tributaries.

Fecundity

No data are available on wild steelhead fecundity.

Age Composition

No data are available on steelhead age structure.

Size

No data are available on wild steelhead.

Sex ratio

No data on Grays River steelhead.

Survival rate

No data available on Grays River steelhead.

JUVENILE LIFE HISTORY

Egg

No data are available on egg production, egg to smolt survival, or emergence timing.

Juvenile rearing

Juvenile rearing for the majority of wild smolts lasts approximately two years prior to ocean emigration. Wild steelhead smolts emigrate in April and May, peaking in early May.

Hatchery releases

Smolts were originally released into the Grays River in 1957 from Chambers Creek stock and although **Cowlitz** River fish were released for several years in the **1960's**, Chambers Creek and Beaver Creek stocks have been the hatchery-stocks released into the Grays River for the past ten years 1981-1990 (Table 3).

Straying

No data on Grays River.

BIOCHEMICAL-GENETIC CHARACTERISTICS

No data are available on Grays River steelhead.

DISEASES

Disease history for hatchery smolts planted in the Grays River is presented in Table 4.

ELOCHOMAN SUBBASIN

Fall Chinook

GEOGRAPHIC LOCATION

The Elochoman River originates in the Willapa Hills (southwest Lewis County and northeast Cowlitz County), and flows in a generally southwest direction into Wahkiakum County meeting the Columbia River at River Mile (RM) 38. Elochoman (also commonly spelled Elokomin) Hatchery is located at RM 9, approximately seven miles northwest of Cathlamet.

ORIGIN

A native population of fall chinook was in existence on the Elochoman River prior to construction of the Elochoman River Salmon Hatchery in 1953. Mixing of stocks very likely began to occur when hatchery supplementation was initiated in 1950 with the release of 70,000 tule fall chinook fingerlings (WDF, 1990). This supplementation and hatchery brood stock were a mix of local stock and transfers from other hatcheries, primarily Spring Creek Hatchery. Brood stock for the Elochoman Hatchery are collected at a weir located near tidewater and the remaining adults are passed upstream to spawn naturally. It is presumed there are no differences between hatchery stock and naturally spawning populations, as no effort was, nor is, being made to keep them separate.

DISTRIBUTION

Natural production occurs mainly in the lower river above tidewater, but will also occur throughout the river up to the hatchery dam at RM 9.2, depending on water flows.

PRODUCTION

Hatchery production is the dominant component in the Elochoman River although some natural production also occurs. In recent years, surplus fall chinook returning to Elochoman Hatchery have been collected for other lower river hatcheries.

Tables 1 and 2 describe the amount of spawning and rearing habitat, by quality, available in the Elochoman River. This data was derived from the Presence/Absence database of Northwest Power Planning Council, 1991.

The Elochoman River adult fall chinook natural spawn escapement from 1977 - 1984 brood years averaged 806 with a low return of 104 for the 1977 brood and a peak of 3,557 for the 1984 brood. Natural spawn escapements by age and brood year are presented in Table 3.

Elochoman Hatchery adult fall chinook returns from 1978 - 1984 brood years averaged 2,907 with a low return of 796 for the 1978 brood and a peak of 9,476 for the 1984 brood. Hatchery returns by age and brood year are presented in Table 4.

Elochoman River tributary sport catch estimates between 1981 - 1988 return years averaged 95 adult fall chinook, ranging from a low of 41 in 1988 to a high of 236 in 1985, based on punchcard and limited actual sampling data. However, specific age and brood year analysis for Elochoman River sport catch is unavailable.

ADULT LIFE HISTORY

Run size, catch and escapement

Ocean commercial and recreational fisheries from Alaska to Washington, in addition to Columbia River gill net and sport fisheries all harvest a portion of the Elochoman River origin fall chinook. Columbia River sport and commercial fisheries are managed to ensure attainment of hatchery egg-take requirements.

Strays from other lower river hatcheries are not unusual. Table 5 lists Elochoman Hatchery origin fall chinook stray coded wire tag recoveries beginning with the 1978 brood through to the 1988 brood, and Table 6 lists the coded wire tags recovered within the Elochoman **subbasin** which originated outside the Elochoman subbasin.

Time of Migration

Adults enter the Elochoman River between September and November.

Spawning Period

Natural spawning occurs between late September and mid-November, usually peaking in mid-October.

Soawnine Areas

Natural production occurs mainly in the lower river above tidewater, but will also occur throughout the river up to the hatchery dam at RM 9.2, depending on water flows.

Age composition

Age ranges from two-year-old jacks to six-year-old adults with three-year-olds or four-year-olds usually the dominant age class. Total age composition data is summarized in Tables 3 and 4. Table 7 lists the age composition percentages by brood year and freshwater-ocean rearing for fall chinook returning to the Elochoman River spawning grounds. Table 8 lists the age composition percentages by brood year and **freshwater.ocean** rearing for fall chinook returning to the Elochoman Hatchery.

Sex Ratio

Female fall chinook comprised 34 - 59 percent of the natural spawners in the Elochoman River between 1981 - 1984 brood years. The percent females by brood year and freshwater-ocean rearing ages for Elochoman River natural spawners are presented in Table 9.

Female fall chinook comprised 44 - 48 percent of the fall chinook returning to the Elochoman Hatchery between 1981 - 1984 brood years. The percent females by brood year and **freshwater.ocean** rearing ages for Elochoman Hatchery returns are presented in Table 10.

The mean fork length by brood year, sex, and **freshwater.ocean** rearing ages of Elochoman River natural spawners for 1979 - 1984 brood years are available in Table 11 and 12. The mean fork length by brood year, sex, and **freshwater.ocean** rearing ages for Elochoman Hatchery returns from 1978 - 1988 brood years are available in Table 13 and 14.

Fecundity

Fecundity at the Elochoman Hatchery between 1983 - 1990 return years averaged 4,204 and ranged from a low of 3,504 in 1987 to a high of 4,395 in 1989. Elochoman River natural spawn and Elochoman Hatchery fecundity data by age and brood year is unavailable.

JUVENILE LIFE HISTORY

Time of Emergence

Emergence times were estimated to be early April for naturally spawning fry, depending on time of egg deposition and water temperatures (Howell et. al., 1985).

Time, age and size at migration

Hatchery release information for the Elochoman **subbasin** by brood year is presented in Table 15. Length data of natural fall chinook smolts from the Elochoman River is unavailable. The number of natural juvenile fall chinook salmon that migrate from the Elochoman River is also unavailable.

Survival Rate

Data not available.

BIOCHEMICAL-GENETIC CHARACTERISTICS

Schreck et al. (1986) determined from electrophoresis that Bonneville Hatchery fall chinook and Spring Creek Hatchery (**BPH**) had 11 similar isozyme gene frequencies and none dissimilar. They did not, however, analyze fall chinook from the Elochoman Hatchery.

DISEASE

Bacteria and parasitic diseases found in the Elochoman Hatchery are listed in Table 16. (WDF Salmon Culture, Olympia).

1988	21						

Age based on scale reading analysis.

1990 return year excludes 30 adults that were trapped in Mill Creek and spawned at the Elochoman Hatchery.

1987 return year includes 879 adults that returned to the Elochoman Hatchery and were spawned at the Grays River Hatchery.

1985 return year includes 350 fish that returned to Elochoman Hatchery and were spawned at the Grays River Hatchery.

1983 return year includes 746 fish that returned to Elochoman Hatchery and were spawned at the Grays River Hatchery.

1980 return year age composition unavailable.

Bacteria	Elochoman	<i>Yersinia ruckeri</i> (Enteric Redmouth)

ELOCHOMAN SUBBASIN

Coho Salmon

GEOGRAPHIC LOCATION

The Elochoman River originates in the Willapa Hills (southwest Lewis County and northeast Cowlitz County), and flows in a generally southwest direction into Wahkiakum County meeting the Columbia River at River Mile (RM) 38. Elochoman (also commonly spelled Elokomin) Hatchery is located at RM 9, approximately seven miles northwest of Cathlamet.

ORIGIN

A native population of **coho** was noted to be in existence in the Elochoman River prior to construction of the Elochoman Salmon Hatchery in 1953. Most existing early **coho** (Type-S) hatchery programs are considered to be linked to native Toutle River stock **coho**. Washington stations either received Toutle stock eggs or utilized local native early run **coho**. Late stock **coho** (Type-N) are informally considered synonymous with Cowlitz River stock **coho**. Late stock hatchery programs were developed utilizing Cowlitz River stock, their derivatives, or native late runs. Late **coho** used in most of the current programs are presumably a blend of all of these, although egg transfers from Cowlitz Hatchery occur most frequently (Howell et al. 1985). The current method for obtaining brood stock is to divert all **coho** in the main river into a hatchery holding pond until management goals are met.

DISTRIBUTION

Natural spawning occurs in most areas accessible to **coho**. When hatchery escapement goals are met the ladder at the barrier dam is opened and all remaining fish are able to pass through and spawn naturally.

PRODUCTION

In Washington and Oregon adult production of early and late **coho** from natural spawners is unknown except for a few instances. A factor of 10 - 15 percent might be considered reasonable for the percent of the total Columbia River **coho** production originating from naturally spawning fish (Howell et al. 1985). Hatchery production is the dominant component in the Elochoman River although some natural production also occurs.

Tables 1 and 2 describe the amount of spawning and rearing habitat, by quality, available in the Elochoman River. This data was derived from the Presence/Absence database of the Northwest Power Planning Council, 1991.

The number of Elochoman River **coho** natural spawn escapement is unavailable. Elochoman Hatchery **coho** returns from 1978 - 1988 brood years averaged 7,144 with a low return of 1,094 for the 1980 brood and a peak of 14,000 for the 1979 brood. Hatchery returns by age and brood year are presented in Table 3.

Elochoman River tributary sport catch estimates between 1981 - 1988 return years averaged 1,183 adult **coho**, ranging from a low of 94 in 1987 and a high of 2,626 in 1982 based on punch card records and limited sampling data. However, specific age and brood year analysis for Elochoman River sport catch is unavailable.

ADULT LIFE HISTORY

Run size, catch and escapement

Ocean commercial and recreational fisheries off the Oregon coast are the primary harvesters of early **coho**. The Oregon troll fishery accounts for the highest percentage of the overall catch. Most of the freshwater recreational harvest occurs in the Washington tributaries (Howell et al. 1985).

Based on coded-wire tagged releases of 1976 - 1978 brood late **coho**, most of the harvest occurs in the Washington and Oregon ocean fisheries. Late **coho** have a more northerly migration pattern than early **coho** (WDF, 1990). This is reflected in the catch distribution where the Washington coastal catch comprised 40 percent of the total harvest compared to 20 percent for early **coho** during 1979 - 1981. Late **coho** also contribute significantly to the lower Columbia River commercial gill net fishery (Howell et al. 1985).

Strays from other lower river hatcheries are not unusual. Table 4 lists Elochoman Hatchery origin **coho** stray coded-wire tag recoveries beginning with the 1978 brood through to the 1988 brood. Table 5 lists the coded-wire tags recovered within the Elochoman **subbasin** which originated outside the Elochoman subbasin.

Harvest rates have averaged 79 percent and 85 percent for Type-S and N stocks, respectively, between 1983 and 1987. Harvest of Type-S **coho** is occasionally constrained by one or more of the fall chinook stocks. Harvest of Type-N **coho** is generally not constrained by weak stocks, with hatchery escapement being the only management constraint (WDF, 1990).

Time of Migration

Early **coho** enter the Columbia River by mid-August and begin returning to the lower Columbia hatcheries in early September. In the **mainstem** Columbia River early **coho** predominate from August to mid-September. Stock composition shifts to late **coho** in late September and October. Typically, the late **coho** run begins entering freshwater in mid to late September with mid-October considered the main migratory period in the **mainstem** Columbia River (Howell et al. 1985).

Spawning Period

For Type-S **coho**, both hatchery and natural spawning occurs around late October, while for Type-N **coho** spawning will extend from late November through March, with the bulk being in December and early January (Howell et al. 1985)

Spawning Areas

Natural spawning occurs in most areas accessible to **coho** (Howell et al. 1985).

Age composition

Coho return as two-year-old jacks and three-year-old adults. Specific age composition percentage (freshwaterocean) by brood year for **coho** spawning naturally and hatchery returns are unavailable.

Sex Ratio

Accounting for the differential harvest of adult males and females in the gill net fishery, the adult

run entering the Columbia River was estimated to be 46 percent females in 1982 and 30 percent females in 1983. Hatchery adult returns were 33 percent females in 1982 and 34 percent females in 1983 (Howell et al. 1985). Specific percent females by brood year and age class (~~freshwater.ocean~~) for **coho** spawning naturally and hatchery returns are unavailable.

Fecundity

Type-S stock **coho** fecundity at the Elochoman Hatchery for 1980, 1981, and 1988 return years averaged 2,558 and with a low of 1,966 in 1988, 2,508 in 1981 and a high of 2,853 in 1980.

Type-N stock **coho** fecundity at the Elochoman Hatchery for 1980 - 1990 return years, excluding 1981, averaged 2,460 and ranged from a low of 2,070 in 1989 to a high of 2,810 in 1980.

Elochoman River natural spawn and Elochoman Hatchery fecundity by age class and brood year is unavailable.

JUVENILE LIFE HISTORY

Time of Emergence

The juvenile life history for Elochoman **subbasin coho** is similar to that of other stocks in the region with a spring emergence (WDF, 1990).

Time, age and size at migration

Freshwater rearing generally lasts for about 14 months. Hatchery release information for the Elochoman **subbasin** by brood year is presented in Table 6. Based on coded-wire tag recovery studies by Dawley et al. (1982), arrival in the Columbia River estuary occurs soon after hatchery release (Howell et al. 1985). Length data of natural **coho** smolts from the Elochoman River is unavailable. The number of natural juvenile **coho** salmon that migrate from the Elochoman River is also unavailable.

Survival Rate

A generalized recent year smolt to adult survival rate for **coho** was estimated to be 2.5 percent (TAC 1983, Howell et al. 1985).

BIOCHEMICAL-GENETIC CHARACTERISTICS

Data has not been compiled.

DISEASE

Bacteria and parasitic diseases found in the Elochoman Hatchery are listed in Table 7. (WDF Salmon Culture, Olympia).

Table 1 (HB-1). Estimated amount of rearing and spawning habitat, by quality, of the Elochoman River **coho** production area.

Distance/Area	Excellent	Good	Fair ^a	Poor ^a	Unknown	Total	Confidence
Miles (%)	52	00	48	00		14.7	
Acres (%)	62	00	38	00		37.0	

^a Ratings of fair and poor habitat quality may reflect natural physical features such as waterfall barriers, as well as degradation caused by humans.

ELOCHOMAN RIVER SUBBASIN

Hatchery Produced Beaver Creek Summer Steelhead

GEOGRAPHIC LOCATION

Beaver Creek Hatchery is located several hundred yards upstream on Beaver Creek, a tributary of the Elochoman which is located approximately four miles from the mouth of the Elochoman River.

ORIGIN

The Beaver Creek Hatchery steelhead originated from **Skamania** hatchery stock. Hatchery releases of summer steelhead began in the Elochoman in 1982. Summer steelhead are not indigenous to the Elochoman River, no historical evidence of natural production exists for this stock.

PRODUCTION

Production Facilities

Beaver Creek Hatchery contains 10 raceways measuring 4 ft x 30 ft and 20 raceways measuring 10 ft x 80 ft plus a one acre smolt rearing pond and two adult holding ponds. Well water is used for incubation and fry rearing with Beaver Creek and Elochoman River water used for grow-out.

Production Summary

Beaver Creek steelhead are artificially reared in a hatchery environment. Egg capacity currently stands at approximately 1 million eggs (steelhead and trout). Summer steelhead production averaged releases of approximately 39,514 smolts annually from 1982 through 1989.

ADULT LIFE HISTORY

Run size and escapement

No data are available on Beaver Creek steelhead.

Time of migration

Peak returns occur in June and July.

Harvest

Ocean harvest of Beaver Creek steelhead is unknown. A popular fishery exists on the lower Columbia River and although the number of Beaver Creek steelhead caught is not known, some Beaver Creek steelhead are part of the lower Columbia harvest.

Prior to 1983, sport catch of summer steelhead consisted of steelhead strays with catch averaging under 30 fish annually (**Table 1**). Releases of hatchery steelhead into the Elochoman River in 1982 have provided anglers with higher returns of summer steelhead with an average sport catch since 1983 of 573 fish annually (Table 1).

Spawning period

No data are available on Beaver Creek steelhead.

Fecundity

No data are available on summer steelhead.

Age composition

No data are available on summer steelhead.

Size

No data are available on summer steelhead.

Sex ratio

No data are available on summer steelhead.

JUVENILE LIFE HISTORY

Egg

No data are available on egg to smolt survival.

J u v e n i l e

Hatchery smolts are reared in the hatchery environment for one year after which they are planted in April and May at a size of 65 to 115 grams each (4-7 fish per pound).

Straying

No data are available on Beaver Creek steelhead.

Hatcher-v releases

Table 2 outlines hatchery releases of summer steelhead into the Elochoman River.

BIOCHEMICAL-GENETIC CHARACTERISTICS

No data are available on Beaver Creek steelhead.

DISEASES

Disease history for Beaver Creek Hatchery is presented in Table 3.

ELOCHOMAN RIVER SUBBASIN

Naturally Produced Winter Steelhead

GEOGRAPHIC LOCATION

The Elochoman River begins in the Willapa Hills area of southwest Lewis County and northeast Cowlitz County. From its source the river flows southwest joining the Columbia River at river mile **(RM)** 38, just downstream of the town of Cathlamet, Washington. Total drainage area of Elochoman basin is 73.3 square miles.

ORIGIN

The wild winter steelhead stock in the Elochoman River is native, although interbreeding with introduced **Cowlitz**, Chambers Creek and Elochoman hatchery stocks has likely occurred.

DISTRIBUTION

Table 1 lists rearing and spawning habitat, by quality, for Elochoman River steelhead based on estimates from the Northwest Power Planning Council.

Distribution of winter steelhead occurs throughout the **mainstem** including the West, North and East forks and also within tributary streams. Figure 1 illustrates this distribution.

PRODUCTION

Production Facilities

There are two hatcheries located on the Elochoman River, the Elochoman River Hatchery operated by Washington Department of Fisheries which rears fall chinook and **coho** salmon and the Beaver Creek Hatchery operated by Washington Department of Wildlife which rears steelhead and cutthroat trout.

Production Summary

No data are available on natural smolt production.

ADULT LIFE HISTORY

Run Size and Escapement

No data are available on wild run size or escapement, however, creel and trapping operations in the early 1960's provide some information. Watson (1963) estimated run size (wild and hatchery fish) at 2,947 in 1962-63 and 2,537 in 1963-64. A slightly higher count was made by Lavier (1970) who estimated total returns (wild and hatchery) of 3,410 and 3,588 fish for the same run years as Watson. Lucas (1992) estimated wild steelhead escapement in 1991 at 166 fish.

Time of migration

Adult time of entry for wild winter steelhead is generally from January through May with peak returns occurring in March and April.

Harvest

Ocean harvest of Elochoman steelhead is unknown. A popular fishery exists on the lower Columbia River which harvests a large number of steelhead including some Elochoman River steelhead.

Based on permit-card harvest estimates, sport catch from 1980 through 1990 averaged 3,046 fish (wild and hatchery; Table 2). "Wild Release" regulations were imposed on the Elochoman River in 1986, limiting legal harvest to hatchery fish only. .

There are no Indian fishing rights exercised in the Elochoman River subbasin.

Spawning period

Wild steelhead spawning occurs from March through mid-June.

Spawning area

Wild steelhead spawn throughout the Elochoman River and in the North, East and West forks. Spawning areas are considered fair for the first five kilometers of the **mainstem** and the lower sections of most tributaries. Spawning and rearing habitat improve in the upper reaches of the river with spawning surveys conducted in 1991 finding more spawning occurring in the upper portion of the basin.

Fecundity

No data are available on wild steelhead fecundity.

Aee composition

No data are available on Elochoman wild steelhead.

Size

Size data on wild fish is lacking. Watson (1964) separated wild versus hatchery fish on dorsal fin condition and determined the average length of wild winter steelhead to be 27 inches (68.6 cm).

Sex t i o

No current data on wild steelhead. Watson (1964) listed females at 84 percent of a 35 fish sample in 1962-63 and in **1963-64** listed females at 52 percent of a 39 fish sample.

Survival rate

No data are available on Elochoman steelhead.

JUVENILE LIFE HISTORY

Egg

No data are available on wild egg to smolt survival.

Emergence

No data are available on Elochoman steelhead.

Juvenile rearing

Juvenile rearing for the majority of wild smolts lasts approximately two years prior to ocean emigration.

Wild steelhead smolts emigrate in April and May, peaking in early May.

Hatcher-v releases

Smolts released into the Elochoman River are provided by Beaver Creek Hatchery which is located on the Elochoman River. Numbers of fish released into the Elochoman River and data concerning the Beaver Creek Hatchery stock is presented in the adjoining Elochoman River hatchery steelhead report.

Straying

No data are available on Elochoman steelhead.

BIOCHEMICAL-GENETIC CHARACTERISTICS

No data are available on Elochoman steelhead.

DISEASES

No data are available on Elochoman steelhead.

REFERENCES

The references for this section appear at the end of the following steelhead section.

ELOCHOMAN RIVER SUBBASIN

Hatchery Produced Winter Steelhead

GEOGRAPHIC LOCATION

Beaver Creek Hatchery is located several hundred yards upstream on Beaver Creek, a tributary of the Elochoman which is located approximately four miles from the mouth of the Elochoman River.

ORIGIN

The Beaver Creek Hatchery winter steelhead originated from native Chambers Creek steelhead in the 1940's. In the late 1950's native Elochoman steelhead were predominantly used as brood stock although some native steelhead were used from Chambers Creek and to a lesser degree, Cowlitz River steelhead.

PRODUCTION

Production Facilities

Beaver Creek Hatchery contains 10 raceways measuring 4 ft x 30 ft and 20 raceways measuring 10 ft x 80 ft, plus a one acre smolt rearing pond and two adult holding ponds. Well water is used for incubation and fry rearing with Beaver Creek and Elochoman River water used for grow-out.

Production Summary

Beaver Creek winter steelhead are artificially reared in a hatchery environment. Egg capacity currently stands at approximately 1 million eggs (steelhead and trout). Steelhead production averages approximately 150,000 lbs which results in releases of 400,000 to 500,000 smolts annually.

ADULT LIFE HISTORY

Run size and escapement

Hatchery returns and escapement data are limited. For the period 1977 to 1984 the number of steelhead returning to Beaver Creek Hatchery as measured by fish collected in the hatchery fish trap ranged from 537 fish in 1977-78 to 2,148 fish in 1983-84 (Table 1).

Time of migration

Adult time of entry for hatchery steelhead is mid November through February, peaking in December and January.

Harvest

Ocean harvest of Beaver Creek steelhead is unknown.

A popular fishery exists on the lower Columbia River and although the number of Beaver Creek steelhead caught is not known, some Beaver Creek steelhead are part of the lower Columbia harvest.

Sport harvest of hatchery steelhead is primarily a December and January fishery. Prior to the operation of the hatchery, sport harvest occurred throughout the Elochoman River from December through March, with peak harvest occurring in March. With current steelhead returns being predominately hatchery fish and with Beaver Creek Hatchery being only a short distance from the mouth of the Elochoman River, returning hatchery steelhead only travel through the lower river which has resulted in a highly concentrated fishery in the four miles of river between Beaver Creek Hatchery and the mouth of the river. With the vast majority of the river being upstream of the hatchery an attempt to stock fish upstream of the hatchery, to spread out the fishing pressure, has met with little success.

No record of treaty fishing on the Elochoman River.

Spawning period

Hatchery steelhead are spawned at Beaver Creek Hatchery starting in mid-December, peaking in January and tapering off by mid-February.

Spawning area

Hatchery steelhead are spawned within the hatchery complex.

Fecundity

Hatchery steelhead spawned from 1980 through 1990 averaged 2,717 eggs per female (Table 3).

Age composition

Length-frequency data indicates that approximately 70 to 90 percent of hatchery winter steelhead return to Beaver Creek Hatchery as 1. 1 + age class. Based on a modified notation of Narver and Whithler age 1.1+ represents a fish with 1 year of freshwater growth and 1-1/2 years of marine growth.

Size

Hatchery size data from 1983-84 showed returning adults averaged 65.1 cm length with a range from 55.4 cm to 80.0 cm.

Sex ratio

Data on hatchery steelhead trapped at Beaver Creek showed 60 percent female fish returning in 1982-83 while fish returning in 1983-84 were 50.5 percent female (Table 2).

Survival rate

Smolt to adult survival rates, based on hatchery rack returns and sport catch, for Beaver Creek hatchery-stock steelhead planted in the Elochoman River between 1976 to 1984 ranged from 2.06 percent in 1981-82 to 4.46 percent in 1983-84 and averaging 3.15 for the eight year period (Table 4).

JUVENILE LIFE HISTORY

Egg

No data are available on egg to smolt survival.

Juvenile rearing

Hatchery smolts are reared in the hatchery environment for one year after which they are planted in April and May at a size of 65 to 115 grams each (4-7 fish per pound).

Straying

No data are available on hatchery steelhead.

Hatchery releases

Hatchery production at Beaver Creek Hatchery averages approximately 400,000 to 500,000 smolts annually. Beaver Creek hatchery-stock steelhead are released into numerous Washington streams, including Grays River, **Skamokawa** Creek, Elochoman River, Abernathy Creek, Germany Creek, Coal Creek, Coweeman River, Kalama River, Lewis River, Salmon Creek, Washougal River and Big White Salmon River, all are tributaries to the Columbia River.

BIOCHEMICAL-GENETIC CHARACTERISTICS

No data are available on hatchery steelhead.

DISEASES

Disease history for hatchery smolts planted in the Elochoman River is presented in Table 6.

Table 1 (RH-a). Total returns (sport catch and hatchery return) of hatchery winter steelhead to the Beaver Creek Hatchery.

Return Year	Sport Catch ^A	Adults Trapped at Hatchery ^B	Hatchery Run Size ^C
1977-78	2,288	537	2,825
1978-79	1,804	744	2,548
1979-80	3,491	675	4,166
1980-81	2,862	1,111	3,973
1981-82	1,503	557	2,060
1982-83	2,211	649	2,860
1983-84	3,238	2,148	5,386

^ASport catch represents hatchery portion of catch (75% of total catch).

Sport catch within subbasin only.

^BAll adults returning to hatchery fish trap are assumed hatchery fish since all adults examined in 1981-82 and 1982-83 had stubbed dorsal tins.

^CRun size equal to hatchery sport catch and hatchery returns combined although three bias exist: 1) some trapped fish are released and may return to be counted again; 2) some hatchery-stock fish spawn in the river never returning to the hatchery; 3) some hatchery fish are harvested in the Columbia River.

1987-88	42.4
1988-89	41.8
1989-90	52.9

*Data obtained from adults returning to Beaver Creek Hatchery.
Source: Washington Department of Wildlife Annual Production Report 1988-89.

Table 3 (AF-a). Mean fecundity by return year for hatchery winter steelhead returning to Beaver Creek Hatchery.

Return Year	Number Fish*	Eggs per Female ^B
1979-80		3,361
1980-81	323	3,563
1981-82	430	1,985
1982-83	360	2,383
1987-88	218	2,610
1988-89	266	3,142
1989-90	521	2,572
1990-91	146	2,762

*Data based on fish returning to Beaver Creek Hatchery.

^BFecundity determined by dividing total egg take by total females spawned.

Stan Woody, Beaver Creek Hatchery Manager, 1991.

Table 4 (TS-a). Smolt to adult survival rates for Elochoman hatchery winter steelhead.

Return Year	Smolts Planted	s *	Percent Return ^{B C}
1977-78	96,857	2,825	2.92
1978-79	93,988	2,548	2.71
1979-80	107,416	4,166	3.88
1980-81	115,894	3,973	3.43
1981-82	99,964	2,060	2.06
1982-83	109,175	2,860	2.62
1983-84	120,870	5,386	4.46

*Returns include sport catch plus hatchery rack returns.

*Percentages based on hatchery smolts released compared to number of returning adults.

^CSmolt return percentages are not exact due to the following;

- 1). Fish may spawn in the river and not return to the hatchery.
- 2). Fish may be harvested in the Lower Columbia fishery.
- 3). Some fish trapped at the hatchery are released and may be counted twice if they return to the hatchery.

COWLITZ SUBBASIN

Spring Chinook

GEOGRAPHIC LOCATION

The Cowlitz River originates from the slopes and foothills of Mt. Rainier and Mt. Adams and drainage encompasses 2,480 square miles. Upper Cowlitz River major tributaries include the Clear Fork, Muddy Fork, **Tilton**, and Cispus Rivers. Fish migration was blocked from these streams following the construction of **Mayfield** Dam in 1963 at River Mile (RM) 52. In 1968, Mossyrock, another hydroelectric dam, was constructed at RM 66. The Toutle River is the major lower river tributary accessible to spring chinook. Major Toutle River tributaries include the North and South Fork Toutle and Green Rivers. Spring chinook are not found in the Coweeman River, another major lower river tributary. The Toutle River enters the **Cowlitz** at RM 20. The Cowlitz River enters the Columbia River at RM 68 near Longview. The Cowlitz Salmon Hatchery is located 2 miles downstream from **Mayfield** Dam. The Toutle Hatchery is located near the mouth of the Green River.

ORIGIN

Native populations of spring chinook were historically present in the Cowlitz River. Cowlitz River escapement in the early 1950's was estimated to be about 10,400 with the Cispus River (**8,100**), upper reaches of the Toutle River (**400**), **Tilton** River (**200**), and upper Cowlitz (1,700) the major spawning populations (WDF, 1951). On the Cowlitz River between 1962 through 1966, an average of 8,720 adult and 1,208 jack spring chinook were counted at **Mayfield** Dam (Thompson and Rothfus, 1969). Spring chinook in the Cowlitz River are currently hatchery stock. Although some spring chinook spawn naturally in the river, few returning adults originate from natural spawning.

DISTRIBUTION

Historically, spawning surveys indicated all spawning in the **Cowlitz** occurred above **Mayfield**. (WDW, 1990). Washington Department of Fisheries (1951) indicated spawning in the Cowlitz occurred above **Packwood** and in the Cispus River between Iron and East Canyon Creeks. In the **Tilton** River, Thompson and Rothfus (1969) indicated spring chinook were reported in 1945, but subsequent spawning in the **Tilton** River has not been observed for years. From 1974 through 1980, an average of 2,838 spring chinook adults were trucked above **Mayfield** into the **Tilton** and upper Cowlitz Rivers to provide sport fishing opportunity and natural production (Stober, 1986). An average of 260 adult spring chinook were planted in the **Tilton** river from 1975 through 1978 and none thereafter. Since 1981, no spring chinook have been planted above **Mayfield** because of possible risk of IHN virus contamination of water supply at the **Cowlitz** Salmon Hatchery (WDW, 1990).

Currently, heaviest natural spawning occurs in the eight mile stretch between the Cowlitz Salmon and Trout Hatcheries. Minor numbers of naturally spawning chinook are observed below Blue Creek.

PRODUCTION

The Northwest Planning Council's model estimated a smolt capacity of 329,400 smolts for the Cowlitz below **Mayfield** and 788,400 smolts in the Toutle River. Above **Mayfield**, the Northwest Power Planning Council's model estimated 1600,000 smolts could be produced. Easterbrooks (1980) estimated a maximum of **1,157,400** spring chinook smolts could be produced above Cowlitz Falls.

Production from naturally spawning adult chinook and juvenile plants in the **Tilton** River was observed at the **Mayfield** Dam migrant facility. An average of 3,894 spring chinook smolts were counted at **Mayfield** Dam migrant facility between 1978 through 1983 and 1985 (**WDW,1990**).

A salmon hatchery was present in the upper Cowlitz River near the Clear Fork, but was abandoned in 1949 as a rearing station because water temperatures were too low. The station continued to take spring chinook eggs through 1950 for transfer to the Green River Hatchery on the Toutle system. **Spring** chinook reared at Green River Hatchery were planted in the upper Cowlitz River (Howell et al., 1985). Spring chinook juveniles were planted in the **Tilton** River until 1978 while the upper Cowlitz received plants through 1981. **Tilton** River juvenile plants for 1974 through 1978 averaged 739,200 fish while 1979 through 1981 upper Cowlitz plants averaged **1,375,200** fish (Stober, 1986).

Currently, hatchery production is the dominant component in the Cowlitz River although some natural production also occurs. The Cowlitz Salmon Hatchery was completed in 1967 to maintain the spring chinook run at a rack return of 17,300 adults. original hatchery design called for 4 million spring chinook juveniles (fingerlings and yearlings) amounting to 196,590 pounds. Recent production of spring chinook has been 600,000 yearlings and 2.5 million fingerlings amounting to 170,000 pounds. Production has increased for 1990 to **1,056,000** smolts. Brood stock for the **subbasin** has been Cowlitz stock collected via hatchery rack returns except for two 1967 brood Willamette stock releases of **331,200** fingerlings in 1968 and 668,100 yearlings in 1969. The Willamette stock juveniles were in questionable health throughout the rearing period and survived poorly based on returns of a yearling fm-clip group (Howell et al., 1985).

Toutle Hatchery was destroyed by the Mt. St. Helens eruption in 1980. Most Toutle River spring chinook were **reared** in Dear Springs Pond, which was later destroyed when a temporary flood control dam was breached in the winter of 1981 - 1982. Production in 1967 through 1980 averaged 33,800 fingerlings and there was one release of yearlings (**WDW, 1990**). In the Toutle River, most plants were unfed fry and fingerling releases using Cowlitz stock from the Cowlitz Hatchery.

Tables 1 and 2 describe the amount of spawning and rearing habitat by quality, available in the Cowlitz River. This data was derived from the Presence/Absence database of Northwest Power Planning Council, 199 1.

The Cowlitz River spring chinook natural spawn escapement from 1978 - 1984 brood years averaged 340 with a low return of 153 for the 1978 brood and a peak of 641 for the 1984 brood. Cowlitz River natural spawn escapements by age and brood year are presented in Table 3.

Cowlitz Salmon Hatchery spring chinook returns from 1978 - 1984 brood years averaged 13,581 with a low return of 5,323 for the 1982 brood and a peak of 23,045 for the 1984 brood. Cowlitz Salmon Hatchery returns by age and brood year are presented in Table 4.

Cowlitz River tributary sport catch estimates between 1978 - 1984 brood years averaged 6,410 spring chinook, ranging from a low catch of 1,669 for the 1982 brood to a peak of 12,362 for the 1979 brood. Cowlitz River tributary sport catch by age and brood year are presented in Table 5.

The total returns of spring chinook to the Cowlitz River between 1978 - 1984 brood years averaged 20,183, ranging from a low return of 7,331 for the 1982 brood and a high of 31,398 for the 1979 brood. Total returns of spring chinook to the Cowlitz River by age and brood year are presented in Table 6.

No data is available for Toutle River spring chinook natural spawn escapements or hatchery returns since the eruption of Mt. St. Helens. The Toutle River has been closed to salmon angling since the eruption.

ADULT LIFE HISTORY

Run size, catch and escapement

Ocean commercial and recreational fisheries from Alaska to Washington, in addition to Columbia River gill net and sport fisheries all harvest a portion of the Cowlitz River origin spring chinook. Ocean and Columbia river fisheries account for 43 percent of production based on the System Planning Model. Relatively little harvest occurs in the ocean while Columbia river commercial and sport fisheries comprise most of the harvest. However, Howell et al. (1985) notes most of the harvest of two 1976 brood tag groups occurred in the coastal fisheries in Washington (32 percent) and British Columbia (30 percent). In the Cowlitz River from 1975 - 1987, the tributary sport catch averaged 32 percent of the total return. Pre-eruption (1977 - 1979) harvest was distributed as 99 percent Cowlitz and 1 percent Toutle (WDW, 1990). Columbia River sport and commercial fisheries are managed to ensure attainment of hatchery egg-take requirements while minimizing any upper Columbia spring chinook impacts. Toutle Hatchery production was to provide for sport and commercial fisheries.

Strays from lower river hatcheries are not unusual. Table 7 lists **Cowlitz** Hatchery origin spring chinook stray coded wire tag recoveries beginning with the 1978 brood through the 1988 brood, and Table 8 lists the coded wire tags recovered within the Cowlitz **subbasin** which originated outside the Cowlitz subbasin.

Time of Migration

The majority of the run migrates through the lower Columbia River from mid-March to mid-May. Arrival at the Cowlitz Salmon Hatchery trap peaks in late May and early June. Figure 1 illustrates the freshwater life history of spring chinook in the Cowlitz River.

Spawning Period

Spawning extends from late August to early October with peak activity in September.

Spawning Areas

The primary spawning area in the Cowlitz River is the four mile reach downstream of the Cowlitz Salmon Hatchery.

Age Composition

Age ranges from two-year-old mini-jacks to six-year-old adults. In the mid - 1970's, two-year-old spring chinook, informally called mini-jacks comprised a substantial portion of the Cowlitz River run. Modifications in the rearing strategy at Cowlitz Hatchery beginning with the 1977 brood substantially reduced the number of mini-jacks (Howell et al., 1985). Total age composition data is summarized in Tables 3 through 5. Table 9 lists the age composition percentages by brood year and freshwater-ocean rearing for spring chinook returning to the Cowlitz Salmon Hatchery. Table 9 lists the age composition percentages by brood year and freshwater-ocean rearing for spring chinook returning to the Cowlitz River spawning grounds. Table 10 lists the age composition percentages by brood year and freshwater-ocean rearing for spring chinook returning to the Cowlitz Salmon Hatchery. Table 11 lists the age composition percentage by brood year and freshwater-ocean rearing for spring chinook caught in the Cowlitz River sport fishery.

Sex Ratio

Female fall chinook comprised 31 - 45 percent of the spring chinook returning to the **Cowlitz**

Salmon Hatchery between 1980 - 1984 brood years. The percent females by brood year and freshwater-ocean rearing ages for Cowlitz Salmon Hatchery spring chinook returns are presented in Table 12. **Cowlitz** River natural spawn escapement percent females by brood year and **freshwater.ocean** rearing ages is currently unavailable.

The mean fork length by brood year, sex, and **freshwater.ocean** rearing ages of Cowlitz River natural spawn escapement and hatchery returns are currently unavailable.

Fecundity

Cowlitz River natural spawn and Cowlitz Salmon Hatchery fecundity data by age and brood year are unavailable.

JUVENILE LIFE HISTORY

Time of Emergence

No information is available on emergence on naturally produced fry. At Cowlitz Salmon Hatchery emergence occurs primarily in mid to late November.

Time, age and size at migration

Based on scale readings and coded-wire tag recoveries, most of the spring chinook spend over a year in freshwater and migrate downstream in their second spring (Howell et al., 1985). Yearlings begin their downstream smolt migration immediately after release in March and April based on tag recoveries in the Columbia estuary (**Dawley et al. 1979**). Fall release tagged juveniles, based on one 1976 brood coded wire tag group, were not recovered in the estuary until the following spring (Howell et al., 1985).

Hatchery release information for the Cowlitz **subbasin** by brood year is presented in Table 13. Length data of natural spring chinook smolts from the Cowlitz River is unavailable. The number of natural juvenile spring chinook salmon that migrate from the Cowlitz River is also unavailable.

Survival Rate

Cowlitz Salmon Hatchery egg to fry survival was 92.9 percent for 1982 through 1986. Fry to smolt survival was 85.8 percent resulting in an egg to smolt survival of 79.7 percent. Smolt to adult survival of marked yearlings for 1980 through 1983 brood years averaged 2.74 percent and ranged from 0.46 percent to 6.97 percent. However, 1982 - 1983 releases averaged 1.21 percent (**WDW, 1990**). Survival to all catch was estimated to be 5.5 percent for Cowlitz spring chinook (Howell et al., 1985). Cowlitz River **subbasin** natural spawn and Toutle Hatchery survival data are not available.

BIOCHEMICAL-GENETIC CHARACTERISTICS

Milner et al. (1983) measured the genetic distances between Cowlitz and Kalama Falls spring chinook. The within group variation was one of the lowest for 17 different stock group comparisons, indicating a relatively high degree of genetic homogeneity. Shreck et al. (1986) compared their samples to those of Milner et al. (1983) in order to determine if there were any genetic changes in stock between sampling dates. The results indicated a statistically significant difference in isozyme gene frequencies for one enzyme system between the current and historical profiles for both the Cowlitz and Kalama Falls samples. However, the statistical difference in the Cowlitz hatchery comparison may be due to the normal difficulty in interpreting the characteristics of that particular stock enzyme system (isocitrate dehydrogenase) and not due to any stock changes

over time.

DISEASE

Bacteria and parasitic diseases found in the Cowlitz Salmon Hatchery are listed in Table 14. (WDF Salmon Culture, Olympia).

REFERENCES

The references for this section appear at the end of the following chinook section.

Table 14 (TD). Parasites and diseases of spring chinook at the Cowlitz Hatchery.

Disease type	Hatchery	Specific Pathogen
Virus	Cowlitz	IHNV: Infectious Hematopoietic Necrosis
virus	Cowlitz	EIBS: Erythrocytic Inclusion Body Syndrome
Bacteria	Cowlitz	<i>Renibacterium salmoninarum</i> (Bacterial Kidney Disease)
Bacteria	Cowlitz	<i>Yersinia ruckeri</i> (Enteric Redmouth)
Bacteria	Cowlitz	<i>Cytophaga psychrophila</i> (Cold Water Disease)
Bacteria	Cowlitz	<i>Aeromonas Salmonicida</i> (Furunculosis)
Parasite	Cowlitz	Various Ectoparasites, Endoparasites and Myxosporidians
Parasite	Cowlitz	<i>Ceratomyxa shasta</i>

Disease history only represents pathogens isolated at the hatchery and not necessarily a disease outbreak.

COWLITZ SUBBASIN

Fall Chinook

GEOGRAPHIC LOCATION

The Cowlitz River originates from the slopes and foothills of Mt. Rainier and Mt. Adams. The drainage encompasses 2,480 square miles. Upper Cowlitz River major tributaries include the Clear Fork, Muddy Fork, **Tilton**, and Cispus Rivers. Fish migration was blocked to these streams following the construction of **Mayfield Dam** in 1963 at River Mile (RM) 52. In 1968, Mossyrock, another hydroelectric **dam**, was constructed at RM 66. The Toutle and Coweeman Rivers are the major lower river tributaries accessible to fall chinook. The Toutle River enters the Cowlitz at RM 20 and the Coweeman River enters the Cowlitz at RM 2. Major Toutle River tributaries include the North and South Fork Toutle and Green Rivers. The Cowlitz River enters the Columbia River at RM 68 near Longview. The Cowlitz Salmon Hatchery is located 2 miles downstream from **Mayfield Dam**. The Toutle Hatchery is located near the mouth of the Green River.

ORIGIN

The **Cowlitz** River received only one plant of fall chinook between 1951 and 1967 when 203,769 Toutle River origin fingerlings were released into the **Tilton** River in 1952 (**WDW**, 1990). The Cowlitz Salmon Hatchery was completed in 1967 to mitigate for upstream habitat losses. Fall chinook broodstock are collected from the Cowlitz Salmon Hatchery barrier dam except for some of the fish planted in 1968 (Toutle), 1971 (Kalama), and 1981 (Big Creek, Kalama, Bonneville). It is presumed there are no differences between hatchery stock and naturally spawning populations, as no effort was, nor is, being made to keep them separate.

Washington Department of Wildlife (1990) reports the Toutle River has been stocked since at least 1951. After 1967, the stock used was primarily Toutle although some other stocks were used in 1967 (Spring Creek and Big Creek), 1979 (Kalama), and after 1987 (Grays River, Big Creek, Kalama and Washougal).

The Coweeman River received plants of fall chinook from at least 1951 to 1979. Since 1967, stocks included Spring Creek, Washougal, and Toutle (**WDW**, 1990).

DISTRIBUTION

Historically, Cowlitz River fall chinook distribution was from near the mouth to upper tributaries such as the Ohanapecosh and **Tilton** Rivers (Thompson and Rothfus 1969). Fall chinook **redd** counts from 1961 through 1966 indicated 37 percent were found above **Mayfield** (**WDW**, 1990). Currently, heaviest spawning occurs between the Cowlitz Salmon and Trout Hatcheries. This river section contained about 82 percent of the redds counted in 1984, but included Cowlitz Hatchery production fish that spawned naturally (**Devore**, 1987). Redd counts generally decrease downstream to the Kelso Bridge at RM 5. The Mt. St. Helens eruption in 1980 severely impacted any fall chinook spawning areas below the mouth of the Toutle River.

In 1951, the Washington Department of Fisheries estimated 80 percent of the Toutle River fall chinook natural spawning occurred in the lower five miles of the river. Toutle River fall chinook natural spawn distribution for 1964 through 1979 was 4.8 percent Toutle River, 3.8 percent South Fork Toutle, 49.4 percent North Fork Toutle, and 42 percent Green River (**WDW**, 1990). In recent years, Toutle River fall chinook spawning ground index counts have been focused in the Toutle Hatchery area.

Coweeman River fall chinook spawning ground index counts are conducted annually between Mulholland Creek and the Jeep Club Bridge.

PRODUCTION

Hatchery production is currently the dominant component in the Cowlitz River although some natural production also occurs. Cowlitz Salmon Hatchery mitigation goals include 8,300 fall chinook. Original hatchery designs called for 10 million fall chinook juveniles amounting to 66,400 pounds (WDW, 1990).

Toutle River fall chinook are anticipated to be managed as a hatchery stock following the eruption of Mt. St. Helens. The Toutle River has been stocked since at least 1951 with 1 million to 6 million fingerlings released annually until 1980. Toutle production is presently being supplemented with annual production from Beaver Slough on the Green River. In 1987 Toutle Hatchery production was 902,400 fall chinook fingerlings. In 1988, Toutle Hatchery production increased to **2,419,000** fall chinook (WDW, 1990).

The Coweeman River has received plants of fall chinook from at least 1951 to 1979 (WDW, 1990).

Table 1 describes the amount of spawning and rearing habitat by quality, available in the Cowlitz River. This data was derived from the Presence/Absence database of Northwest Power Planning Council, 199 1.

The Northwest Power Planning Council's model showed natural production capacity was **2,183,000** smolts for the Cowlitz River below **Mayfield**. Above Mayfield, the Northwest Power Planning Model estimated 357,000 smolts could be produced from the **Tilton** River and **4,028,000** above Cowlitz Falls. Easterbrooks (1980) estimated a maximum of **4,254,000** fall chinook smolts could be produced upstream from Cowlitz Falls. The Northwest Power Planning Council's model also showed production capacity was **2,799,000** smolts in the Toutle River and 602,000 smolts in the Coweeman River.

Fall chinook in the Cowlitz River were historically abundant. In 1951, the Washington Department of Fisheries estimated 10,900 fall chinook returned to the Cowlitz and 500 fall chinook in the Tilton Rivers. In 1961 through 1966, an average of 5,992 adult and 2,543 jack fall chinook were counted at **Mayfield** Dam (Thompson and Rothfus 1969). From 1983 - 1985, an estimated average of 1,661 natural fall chinook returned to the Cowlitz River (Devore, 1987). The Cowlitz River fall chinook natural spawn escapement from 1978 - 1984 brood years averaged 5,194 with a low return of 2,574 for the 1982 brood and a peak of 11,660 for the 1984 brood. Cowlitz River fall chinook natural spawn escapements by age and brood year are presented in Table 2.

In 1951, the Washington Department of Fisheries estimated escapement of fall chinook in the Toutle River at 6,500 fish. Toutle River fall chinook natural spawning escapement for 1964 through 1979 averaged 6,573 fish (WDW, 1990). The Toutle River, including the **mainstem** Toutle and South Fork Toutle plus Green River fall chinook spawning ground data following Mt. St. Helens eruption is very limited. Toutle River **subbasin** fall chinook natural spawn recent escapements by age and brood year are presented in Tables 3, 4, and 5, respectively.

The Washington Department of Fisheries (1951) estimated escapement of fall chinook in the Coweeman River at 5,000 fish. The Coweeman River fall chinook natural spawn escapement from 1978 - 1984 brood years averaged 279 with a low return of 49 for the 1979 brood and a peak of 1,308 for the 1984 brood. Coweeman River fall chinook natural spawn escapements by age and brood year are presented in Table 6.

Cowlitz River Hatchery fall chinook returns from 1978 - 1984 brood years averaged 9,988 with a low return of 4,405 for the 1978 brood and a peak of 21,589 for the 1984 brood. Cowlitz Hatchery fall chinook returns by age and brood year are presented in Table 7.

Toutle Hatchery fall chinook returns from 1972 through 1979 averaged 4,183 fish (WDW, 1990). The Toutle Hatchery (Beaver Slough Pond) was reopened in 1986 after several years of being closed. The Toutle Hatchery new adult rack, trapping and holding facility became operational in the fall of 1990. The opening of the Toutle Hatchery marked the first hatchery collection and spawning since the Mt. St. Helens eruption in 1980. The recent Toutle Hatchery fall chinook return by age and brood year is presented in Table 8.

Cowlitz River tributary sport catch estimates between 1977 - 1986 return years averaged 2,672 fall chinook, ranging from a low of 407 in 1983 to a high of 4,922 in 1978 based on punchcard data. However, specific age and brood year analysis for Cowlitz River sport catch is unavailable.

The Toutle River has been closed to salmon angling since the Mt. St. Helens eruption.

Coweeman River tributary sport catch is limited to jacks (chinook <24") only. Coweeman River tributary sport catch estimates, though minor, are currently unavailable.

ADULT LIFE HISTORY

Run size, catch and escapement

Ocean commercial and recreational fisheries from Alaska to Washington, in addition to Columbia River gill net and sport fisheries all harvest a portion of the Cowlitz River origin fall chinook. The **System** Planning Model used a combined ocean and Columbia River harvest rate of 87.1 percent (WDW, 1990). In 1980 and 1981, a terminal commercial **gillnet** fishery in the lower Cowlitz River targeted primarily Toutle River fall chinook. Overall, Columbia River sport and commercial fisheries are managed to ensure attainment of hatchery egg-take requirements.

Strays from other lower river hatcheries and natural production are not unusual. Cowlitz and Toutle Hatchery origin fall chinook coded wire tag recoveries beginning with the 1978 brood through to the 1988 brood are listed in Tables 9 and 10, respectively. Table 11 lists the coded wire tags recovered within the Cowlitz **subbasin** which originated outside the Cowlitz subbasin.

Time of Migration

Upstream migration begins from early August to early September. Depending partly on early fall rains and tributary migration distances, recruitment to most hatchery collection sites is usually greatest during the middle of September. The Cowlitz Hatchery **substock** arrives at the collection site slightly later and over a broader time period than other **Lower** River Hatchery stocks. Figure 1 illustrates the freshwater life history of fall chinook in the Cowlitz.

Spawning Period

Cowlitz Hatchery fall chinook are spawned primarily in late October to early November. Natural spawning generally occurs concurrently with the spawning of the hatchery run.

Spawning Areas

Currently, most Cowlitz River fall chinook natural spawning occurs between the Trout Hatchery (RM 41.3) and the Salmon Hatchery (RM 52.0) with fewer numbers found downstream to the Kelso Bridge. In recent years, Toutle River spawning ground counts have been focused in the area near

the Toutle Hatchery, on the Green River.

Coweeman River fall chinook spawning ground index counts are conducted annually between Mulholland Creek and the Jeep Club Bridge, a distance of about 6.0 miles.

Age Composition

Age ranges from two-year-old jacks to six-year-old adults with three-year-olds or four-year-olds usually the dominant age class. Total age composition data is summarized in Tables 2 through 8. Tables 12 and 13 list the age composition percentages by brood year and freshwater-ocean rearing for fall chinook returning to the **Cowlitz** and Coweeman Rivers spawning grounds, respectively. Table 14 lists the age composition percentages by brood year and **freshwater.ocean** rearing for fall chinook returning to the Cowlitz Salmon Hatchery.

Sex Ratio

Female fall chinook comprised 50 - 60 percent of the natural spawners in the Cowlitz River between 1981 and 1984 brood years. Female fall chinook comprised 29 - 75 percent of the natural spawners in the Coweeman River between 1981 and 1984 brood years. The percent females by brood year and **freshwater.ocean** rearing ages for Cowlitz and Coweeman Rivers fall chinook are presented in Tables 15 and 16, respectively.

Female fall chinook comprised 34 - 49 percent of the **fall** chinook returning to the Cowlitz Hatchery between 1981 - 1984 brood years. The percent females by brood year and freshwater-ocean rearing ages for Cowlitz Hatchery returns are presented in Table 17.

The mean fork length by brood year, sex, and **freshwater.ocean** rearing ages of Cowlitz River natural spawners for 1977 - 1985 brood years are available in Table 18 and 19.

The mean fork length by brood year, sex, and freshwater-ocean rearing ages of Coweeman River natural spawners for 1979 - 1984 brood years are listed in Tables 20 and 21.

The mean fork length by brood year, sex, and **freshwater.ocean** rearing ages for Cowlitz Hatchery returns from 1977 - 1984 brood years are available in Tables 22 and 23.

Fecundity

Fecundity at the Cowlitz Hatchery between 1983 - 1990 return years averaged 4,109 and ranged from a low of 3,898 in 1983 to a high of 4,505 in 1990. Cowlitz, Toutle, and Coweeman Rivers natural spawn and Cowlitz and Toutle Hatcheries fecundity data by age and brood year is unavailable.

JUVENILE LIFE HISTORY

Time of Emergence

Emergence times were estimated to be early May for naturally spawning fry, depending on time of egg deposition and water temperatures (Howell et. al., 1985).

Time, age and size at migration

Hatchery release information for the Cowlitz **subbasin** by brood year is presented in Table 24. Length data of natural fall chinook **smolts** from the Cowlitz River **subbasin** is unavailable. The number of natural juvenile fall chinook salmon that migrate from the Cowlitz River **subbasin** is also unavailable.

Survival Rate

Egg-to-fry survival at Cowlitz Salmon Hatchery was 92.9 percent for 1982 - 1986. Fry-to-smolt survival was 94 percent resulting in an egg-to-smolt survival of 87.3 percent. Smolt-to-adult survival of hatchery fish for 1980 - 1983 brood years averaged 0.29 percent with a range of 0.05 percent to 0.56 percent (WDF, 1990). Cowlitz River natural spawn survival data is unavailable.

Prior to 1980, Toutle Hatchery fingerling survival was estimated at 0.57 percent. Fry-to-fingerling survival at Toutle Hatchery was 99.6 percent and 98.4 percent for the 1987 and 1988 releases, respectively. Smolt-to-adult survival for Toutle River fall chinook averaged 0.57 percent (WDF, 1990). Toutle River natural spawn survival data is unavailable.

Coweeman River fall chinook smolt-to-adult survival was estimated to be 0.25 percent (WDF, 1990).

BIOCHEMICAL-GENETIC CHARACTERISTICS

Data not available.

DISEASE

Bacteria and parasitic diseases found in the **Cowlitz** Hatchery are listed in Table 25. (WDF Salmon Culture, Olympia)

Figure 1 (TT). Freshwater life history of fall chinook in the Cowlitz River. The developmental stage timing represents basinwide averages, local conditions may cause some variability.

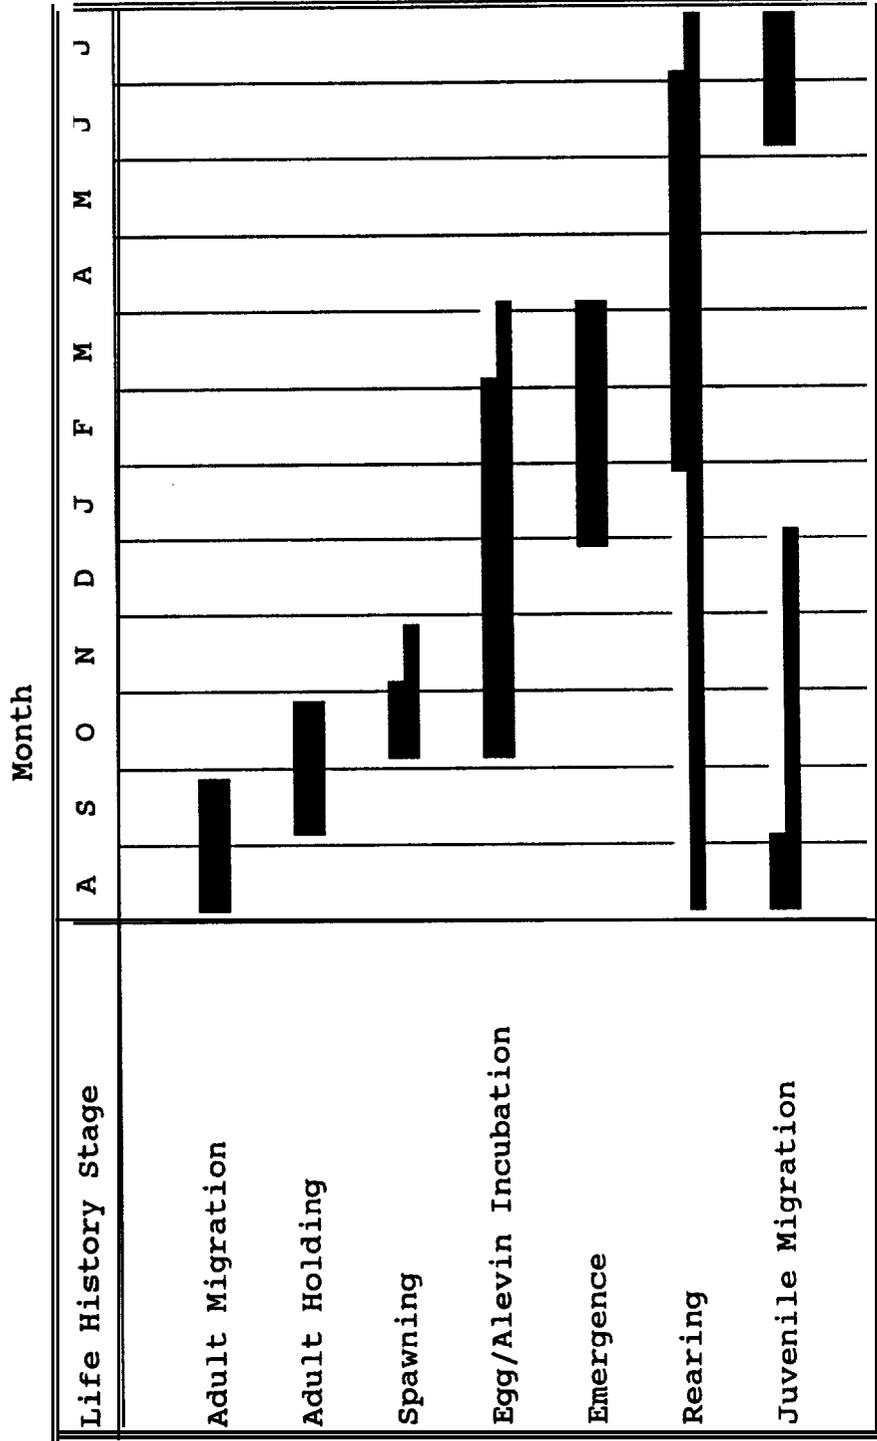

Table 1 (FIB-1). Estimated amount of rearing and spawning habitat, by quality, of the Cowlitz River fall chinook production area.

Distance/Area	Excellent	Good	Fair ^a	Poor ^a	Unknown	Total	Confidence
Miles (%)	0.02	0.40	0.40	0.18		208.8	
Acres (%)	0.02	0.42	0.35	0.21		1186. c	

^a Ratings of fair and poor habitat quality may reflect natural physical features such as waterfall barriers, as well as degradation caused by humans.

COWLITZ SUBBASIN

Coho Salmon

GEOGRAPHIC LOCATION

The Cowlitz River originates from the slopes and foothills of Mount Rainier and Mount Adams. The drainage encompasses 2,408 square miles. Upper Cowlitz River major tributaries include the Clear Fork, Muddy Fork, **Tilton**, and Cispus Rivers. Fish migration was blocked to these streams following the construction of **Mayfield Dam** in 1963 at River Mile (RM) 52. In 1968, **Mossyrock**, another hydroelectric dam, was constructed at RM 66. The Cowlitz River enters the Columbia River at RM 68 near Longview. The Cowlitz Salmon Hatchery is located 2 miles downstream from **Mayfield Dam**.

The Toutle and Coweeman Rivers are the major lower river tributaries accessible to **coho**. The Toutle River enters the Cowlitz at RM 20 and the Coweeman enters the Cowlitz at RM 2. Major Toutle River tributaries include the North and South Fork Toutle and Green Rivers. The Toutle Hatchery was destroyed in the 1980 eruption of Mt. St. Helens. Deer Springs rearing pond was later destroyed by failure of a Corps of Engineers flood control structure in the winter of 1981 - 1982. The present salmon culture facility on the Toutle is the Beaver Slough.

ORIGIN

Native populations of **coho** were historically present in the Cowlitz River. Hatchery **coho** have been planted in the **subbasin** since at least 1915, when the **Tilton River Hatchery** operated downstream of Morton, until 1921. A salmon hatchery also operated in the upper Cowlitz near the mouth of the Clear Fork until 1949 when it was abandoned due to low water temperatures. Currently, brood stock is collected via hatchery rack returns (**WDW, 1990**). Late stock **coho** (Type-N) are informally considered synonymous with Cowlitz River stock **coho**. Late stock hatchery programs were developed utilizing Cowlitz River stock, their derivatives, or native late runs. Late **coho** used in most of the current programs are presumably a blend of all of these, although egg transfers from Cowlitz Hatchery occur most frequently (Howell et al. 1985). Cowlitz river **coho** became known as Type-N for turning north once they reached the ocean.

Native populations of **coho** were also historically present in the Toutle River. Most existing early **coho** (Type-S) hatchery programs are considered to be linked to native Toutle River stock **coho**. These fish provided the basis for **coho** rearing program, which began in 1952 at the Toutle Hatchery on the Green River. The hatchery program was very successful and, consequently, surplus eggs were readily available for transfer to other stations (Howell et al. 1985). Toutle River **coho** became known as Type-S for turning south once they reached the ocean. Since the eruption of Mt. St. Helens, several lower river hatchery brood stock have been used. The sources include Grays River, Cowlitz, Kalama, and Washougal Hatcheries (**WDW, 1990**).

DISTRIBUTION

Historically **coho** were found in all the streams of the Cowlitz River. Recently distribution has been primarily confined below **Mayfield Dam**. A number of lower Cowlitz River small tributaries have good to excellent **coho** production potential. Among these are Olequa, Lacamas, Ostrander, Blue, Otter, Brights, Mill, Arkansas, Foster, and Hill Creeks (**WDF, 1973**). Because **coho** have not been observed to host the IHN virus (infectious hematopoietic necrosis) in the Cowlitz River, **coho** adults are usually released annually in the **Tilton River** and upper Cowlitz River (**WDW, 1990**).

A number of Toutle River small tributaries had good to excellent **coho** potential before Mt. St. Helens eruption in 1980. Among these were tributaries to the North and South Forks Toutle, and

Green Rivers.

PRODUCTION

In 1951, the Washington Department of Fisheries estimated **coho** escapement at about 32,500 fish. In the Cowlitz River, an average of 24,579 **coho** were counted past **Mayfield** for 1961 through 1966 (Thompson and Rothfus, 1969). More than 15,700 **coho** were released upstream from the Cowlitz Hatchery annually to spawn naturally from 1967 through 1971 (**WDF**, 1973). Cowlitz Salmon Hatchery was completed in 1967. Presently, most **coho** in the Cowlitz River are of hatchery origin (**WDW**, 1990). Of the 4,635 Cowlitz River naturally spawning **coho** in 1985, an estimated 91 percent were thought to have originated from hatchery smolt releases (Devore, 1987). Hatchery fingerling releases could account for the additional natural fish. From 1983 through 1988 an average of 1,929 adults, mostly males, were planted into the **Tilton** River whereupon they tended to drop downstream out of the **Tilton** (Stober, 1986).

Toutle River **coho** were historically abundant. Toutle River run size of natural **coho** for 1972 through 1979 was estimated at 1,743. Coho returns to the Toutle River are rebuilding since the 1980 volcanic eruption of Mount St. Helens. Planting of fingerlings began in 1983. In 1990, the Toutle River Hatchery reported a return of 2,754 adults and 1,491 jacks.

Little is known of the historic or present status of Coweeman River **coho**. The Washington Department of Fisheries (1951) felt the Coweeman was underescaped due to the presence of splash dams blocking production areas. Run size was roughly estimated at 300 hatchery fish and 200 natural fish (**WDW**, 1990).

Tables 1 and 2 describe the amount of spawning and rearing habitat, by quality, available in the Cowlitz River. This data was derived from the Presence/Absence database of the Northwest Power Planning Council, 1991.

The Northwest Power Planning Council's model estimated smolt production capacity of 123,123 fish for the lower Cowlitz River. Above **Mayfield** on the Cowlitz River, the Northwest Power Planning Council's model estimated 131,318 smolts could be produced in the **Tilton** River and Winston Creek, while 155,018 could be produced above Cowlitz Falls, for a total of 286,336 smolts in the upper watershed. Easterbrooks (1980) estimated maximum **coho** production above Cowlitz Falls at 2,696,800 smolts.

Toutle River natural production capacity was estimated at 142,234 smolts. Present production of natural fish is depressed mainly from habitat degradation from the volcano (**WDW**, 1990).

Natural production capacity in the Coweeman River was estimated to be 37,797 smolts (**WDW**, 1990).

The **Cowlitz** Hatchery was completed in 1967 to maintain the **coho** run at a mitigation level of 25,500 adults to the hatchery rack. Original hatchery designs called for 5 million **coho** smolts totaling 231,820 pounds (**WDW**, 1990).

Cowlitz River subbasin, including the Toutle and Coweeman Rivers, **coho** natural spawn escapement is unavailable except for 1985. In 1985 an estimated 4,635 **coho** naturally spawned in the Cowlitz River (**Devore**, 1987).

Cowlitz Hatchery **coho** returns from 1978 - 1988 brood years averaged 39,576 with a low return of 20,481 for the 1987 brood and a peak of 70,401 for the 1983 brood. Cowlitz Hatchery returns by age and brood year are presented in Table 3.

From 1972 through 1979, Toutle Hatchery returns averaged 14,406 adults and 702 jacks, a total return of 15,108 fish (Ring, 1987). Toutle Hatchery returns for 1990 by age and brood year are presented in Table 4.

The Cowlitz River tributary sport catch estimates between 1979 through 1988 return years averaged 1,774 adult **coho** ranging from a low of 604 in 1983 to a high of 4,621 based on punch card and limited actual sampling data. However, specific age and brood year analysis for Cowlitz **coho** tributary sport catch is unavailable.

The Toutle River sport catch was entirely **coho** during 1967 - 1968 (WDF, 1973). For 1977 through 1979, harvest in the Toutle averaged 1,061 fish. The Toutle and Coweeman Rivers have been closed to adult sport harvest since 1981. Specific age and brood year analysis for Toutle and Coweeman tributary sport catch is unavailable.

ADULT LIFE HISTORY

Run size, catch and escapement

Ocean commercial and recreational fisheries off the Oregon coast are the primary harvesters of early **coho**. Hager and Hopley (1981) found harvest of both early **Cowlitz** and **Toutle coho** stocks contributed more south of the Columbia River as compared to late **Cowlitz coho** which contributed more north of the Columbia. The early component of **Cowlitz coho** is somewhat more southerly distributed in the ocean than the late **Cowlitz** component but generally not far south a the **Toutle** stock. The Oregon troll fishery accounts for the highest percentage of the overall catch of early **coho**. The System Planning Model estimated 73.1 percent of total **coho** production was harvested in the ocean and Columbia River.

Harvest rates have averaged 79 percent and 85 percent for Type-S and N stocks, respectively, between 1983 and 1987. Harvest of Type-S **coho** is occasionally constrained by one or more of the fall chinook stocks. Harvest of Type-N **coho** is generally not constrained by weak stocks, with hatchery escapement being the only management constraint (WDF, 1990). A commercial gill net fishery occurred in the lower **Cowlitz** in 1980 and 1981. The catch was 6,618 and 2,764 **coho** respectively.

Strays from other lower river hatcheries are unusual. Table 5 lists **Toutle** Hatchery origin stray coded wire tag recoveries beginning with the 1978 brood through the 1988 brood. Tables 6 and 7 list the coded wire tags recovered within the **Cowlitz** and **Toutle** Rivers, respectively, which originated outside the **Cowlitz** subbasin.

Time of Migration

Early **coho** enter the Columbia River by mid-August and begin returning to the lower Columbia hatcheries in early September. In the **mainstem** Columbia River early **coho** predominate from August to mid-September. Stock composition shifts to late **coho** in late September and October. Typically, the late **coho** run begins entering freshwater in mid to late September with mid-October considered the main migratory period in the **mainstem** Columbia River (Howell et al. 1985). Both Type-S and Type-N **coho** exist in the **Cowlitz** subbasin. At the **Cowlitz** Hatchery all **coho** are considered Type-N stock.

Spawning Period

For Type-S **coho**, both hatchery and natural spawning occurs around late October, while for Type-N **coho** spawning will extend from late November through March, with the bulk occurring in December and early January (Howell et al. 1985).

At Cowlitz Hatchery, fish are selected by arrival time with 10 percent of the eggs selected from mid-September to mid-October returning adults, 80 percent from mid-October through November arriving adults, and 10 percent from adults arriving after November. For 1989, 20 percent, 70 percent, and 10 percent of eggs were taken from the early, middle, and late group, respectively (WDW, 1990).

Spawning Areas

Natural spawning occurs in most areas accessible to **coho**, especially the **Olequa**, Lacamas, Brights, Stillwater, Campbell, and Delameter drainages. From 1983 through 1985, an average of 1,929, mostly adult males, were planted into the **Tilton** River.

Age composition

Coho return as two-year-old jacks and three-year-old adults. Few **coho** exceed two summers in the ocean; of 170 marked groups, only eight had any fish return with a third summer in salt water (WDW, 1990). Specific age composition percentage (freshwater:ocean) by brood year for **coho** spawning naturally and hatchery returns are unavailable.

Sex Ratio

Saltwater age composition of hatchery **coho** in 1977 through 1986 was based on hatchery returns which were 38 percent 1-year ocean jacks, 40.2 percent 2-year ocean males, and 21.8 percent 2-year ocean females (WDW, 1990).

Mean fork length of adult returns from Cowlitz N stock for 1968 through 1971 releases was 66.3 cm. Mean lengths of jacks in 1982 through 1984 was 36.4 cm. Mean fork length of Cowlitz N stock in the Columbia River net fishery was 64.9 cm and 68.1 cm in 1971 and 1972, respectively (Hager and Hopley, 1981). However, Cowlitz River hatchery returns and natural spawn escapement mean fork length by brood year and freshwater:ocean rearing ages is unavailable.

Mean length of the 1967 (Hager and Hopley, 1981) and 1972 (Seidel and Mathews, 1977) brood Toutle **coho** averaged 68.9 cm. The 1972 brood averaged 67.9 cm at the hatchery. However, Toutle River hatchery returns and natural spawn escapement mean fork length by brood year and freshwater:ocean rearing is unavailable.

Fecundity

Fecundity of **coho** spawned from 1982 through 1987 averaged 2,578 eggs per female (n= 34,623) at the Cowlitz Hatchery (WDW, 1990). Cowlitz River natural spawn escapement and hatchery return fecundity by freshwater:ocean rearing and brood year is unavailable.

For 1975 through 1979, fecundity averaged 2,632 eggs per female for Toutle River **coho** (WDW, 1990). Toutle River natural spawn escapement and hatchery returns fecundity by **freshwater:ocean** rearing and brood year is unavailable. Coweeman River natural spawn escapement fecundity is also unavailable.

JUVENILE LIFE HISTORY

Time of Emergence

Fry emergence in the Cowlitz River occurs from January through April (WDW, 1990). Early **coho** emergence time depends primarily on the temperature of the water in the stream. At 50 degrees F, fertilization to eyed-egg stage takes about 3.5 weeks, eyed-egg to hatching about 2.5 weeks, and

hatching to emergence about 8 weeks (Howell et al. 1985).

Time, age and size at migration

Hatchery release information for the Cowlitz **subbasin** by brood year is presented in Table 9. The Cowlitz Salmon hatchery plants about 4.8 million yearling smolts annually while over 1 million smolts were planted into the Toutle from the Toutle Hatchery prior to the eruption. In addition, from 1984 through 1987, releases of fry and fingerlings averaged **2,310,400** fish in Cowlitz tributaries, 309,500 in the Cowlitz mainstem, 755,900 in the Toutle watershed, and 252,700 fish in the Coweeman watershed (WDW, 1990).

To provide a sport fishery in the reservoirs prior to 1986, about 600,000 and 2.3 million fingerlings at about 100 to 200 fish per pound were planted from the Cowlitz hatchery into **Mayfield** and Riffe Lakes, respectively. Since 1986, **coho** plants into **Mayfield** Lake have been terminated and Riffe Lake plants have been reduced to 1.2 million fish. **Mayfield** Lake plants were terminated after 1985 when an average of 0.34 percent and 0.14 percent of **Mayfield** Lake and **Tilton** River planted marked fish were caught, respectively (Tipping, 1988).

In recent years, some smolts were produced in the upper Cowlitz by trucking adults and juveniles above **Mayfield** into the **Tilton** River and **Mayfield** Lake. However, the adults planted in the **Tilton** River tended to drop downstream from the **Tilton** (Stober, 1986). Juvenile **coho** in the lake could emigrate downstream through a migrant facility at the dam into the lower river. Of the juveniles released into the lake and river, 2.60 percent and 2.03 percent, respectively, passed through the migrant trap (Tipping, 1988). The number of smolts counted at the dam from 1978 through 1989 (except 1984) averaged 8,246 smolts ranging from a low of 145 in 1989 and a high of 17,150 in 1986. The juveniles observed at the outmigrant trap after **Mayfield** Lake and **Tilton** River juvenile plants ceased in 1985 were probably offspring from adults released into the **Tilton** River and/or juveniles originally released into Riffe Reservoir (WDW, 1990).

Based on coded-wire tag recovery studies by Bottom et al. (1984), arrival in the Columbia River estuary occurs soon after hatchery release. Releases of coded wire tagged 1978 and 1979 brood Toutle **coho** were recovered at Jones Beach and McGowan in the Columbia River estuary only a few weeks after release. The 1978 and 1979 brood Toutle **coho** migration rates averaged 8 km/day and 10.5 km/day based on coded wire recoveries from Jones Beach and McGowan, respectively. Jones Beach is located at Columbia River Kilometer (RM) 46.6 and McGowan is at (RM) 10.

Juvenile early run **coho** have been caught in the ocean primarily off Oregon in may through July and off southern Washington in September during their first summer in the ocean. Ocean distribution of coded wire tagged early run juvenile **coho** were sampled with purse seines during 1981-84 (Howell et al. 1985).

Length data of natural **coho** smolts from the Cowlitz River **subbasin** is unavailable. The number of natural juvenile **coho** salmon that migrate from the lower Cowlitz, Toutle, and Coweeman Rivers are also unavailable. During sampling of juvenile **coho** populations in select tributaries, heaviest abundance of juvenile **coho** on the Cowlitz River was found between RM 12 to 14 on Lacamas Creek, a small tributary to the Cowlitz River at RM (WDF, 1973).

Survival Rate

Cowlitz Hatchery egg-to-fry survival was 95.1 percent for 1982 through 1986. Fry-to-smolt survival was 89.5 percent resulting in an egg-to-smolt survival of 85.1 percent. Smolt to adult survival of marked production fish for 1981 through 1983 brood years ranged from 1.67 percent to 7.14 percent and averaged 3.65 percent. Smolts released to adult hatchery returns averaged 0.57 percent for the 1981 through 1986 releases. Performance of fry and fingerling releases is unknown

in the Cowlitz and Coweeman Rivers (WDW, 1990).

On the Toutle River egg-to-fry survival averaged 90.6 percent for the 1978 and 1979 broods. Fry-to-smolt survival for the 1978 brood averaged 86.2 percent, resulting in an egg-to-smolt survival of 78.1 percent (WDW, 1990). Smolt-to-adult survival of fish released in April and May 1974 at 18 to 21 fish per pound averaged 4.11 percent (Seidel and Mathews, 1977). For the 1979 release, smolt-to-adult survival averaged 4.32 percent (WDW, 1990). Spring-to-fall survival in three nearly barren post-eruption Toutle tributaries averaged 20.2 percent (Bisson et al. 1988). The purpose of the releases was to supplement natural production.

BIOCHEMICAL-GENETIC CHARACTERISTICS

Hjort and Shreck (1982) compared the phenotypic characters (isozyme gene frequencies, life history and morphology) of **coho** salmon from Oregon, Washington, and California using agglomerative and divisive cluster analyses. Early **coho** from Bonneville, Big Creek, and Sandy River hatcheries were profiled along with Cowlitz Hatchery late **coho**. Although Columbia River **coho** tended to cluster together within broad comparisons, further segregation into early and late stocks did not occur.

DISEASE

No IHN positive **coho** have been isolated at Cowlitz Hatchery. Low temperature disease (*Cytophaga psychrophillia*) has been rated the most severe pathogen, followed by bacterial hemorrhagic septicemia and enteric **redmouth** (*Yersinia ruckeri*) (WDW, 1990). Bacteria and parasitic diseases found in the Cowlitz Hatchery are listed in Table 10. (WDF Salmon Culture, Olympia).

Table 1 (HB-1). Estimated amount of rearing and spawning habitat, by quality, of the Cowlitz River **coho** production area.

Distance/Area	Excellent	Good	Fair'	Poor ^a	Unknown	Total	Confidence

COWLITZ RIVER SUBBASIN

Hatchery Produced Summer Steelhead

GEOGRAPHIC LOCATION

The Cowlitz River is located in southwest Washington, within Lewis and Cowlitz Counties. From its headwaters in the Cascade Mountains the Cowlitz River flows southwesterly joining the Columbia River at river mile (RM) 68. Total drainage encompasses approximately 2,480 square miles and includes the major tributaries of the Toutle River, with a drainage of 512 square miles joining the Cowlitz at RM 20, and the Coweeman River, with a drainage of 127 square miles joining the Cowlitz at RM 1.7.

ORIGIN

Summer steelhead within the Cowlitz **Subbasin** are an introduced stock. The Cowlitz broodstock was derived from **Skamania** hatchery-stock steelhead, but starting in the early 1970's summer steelhead returning to the Cowlitz River were used to develop the **Cowlitz** hatchery-stock. Historically, the Cowlitz River did not support a native summer steelhead run although summer steelhead do reproduce naturally in the subbasin; these fish are hatchery origin steelhead or strays which successfully spawned in the subbasin. Wild summer steelhead within the **subbasin** constitute a small portion of the total. In 1980 and 1981, natural summer steelhead contributed a mean 8.7 percent of sampled adults (Tipping 1981; 1982). In another survey taken in 1981 on the Toutle River, 6.9 percent of sampled adults were natural fish (**Schuck** and Kruse 1982).

DISTRIBUTION

Table 1 lists spawning and rearing habitat, by quality, for Cowlitz River steelhead based on estimates from the Northwest Power Planning Council.

Summer steelhead within the **Cowlitz Subbasin** are primarily hatchery fish with few natural fish present. Natural summer steelhead which spawn in the **subbasin** are limited to the Cowlitz River below **Mayfield** Dam with some fish also entering the Toutle River.

PRODUCTION

Production Facilities

The Cowlitz Trout Hatchery located on the Cowlitz River at RM 42 is the only facility producing steelhead (summer and winter) in the subbasin. The hatchery consists of 104 hatching troughs, eight 10 ft. x 100 ft. raceways, twenty-four 20 ft. x 90 ft. raceways and four five acre rearing ponds. Water is supplied by nine wells and pumped river water (river water supplies over 90 percent of the total water used). Well water is used for egg incubation and fry rearing. *Ceratomyxa shasta*, a prevalent fish pathogen which has caused severe fish losses at Cowlitz **Hatchery**, has resulted in the installation of an ozone water treatment system to disinfect up to 20 cfs of the hatchery water supply.

Production Summary

Production from the small number of summer steelhead which spawn naturally is not known. Hatchery adults are spawned at the Cowlitz Hatchery. Cowlitz Hatchery summer steelhead production, as measured by number of steelhead smolts released, for 1987 through 1991 was 56,908 in 1987, 82,153 in 1988, 222,764 in 1989, 254,681 in 1990, and 268,954 in 1991. For the 1980's mortality of hatchery fish from the fish pathogen *C. Shasta* often limited production with mortality

ranging as high as 80 percent. These high fish losses led to the installation of a new ozone water treatment system. Although the system has only been operating a short time, early indications show a vast reduction in mortality.

ADULT LIFE! HISTORY

Run Size and Escapement

Steelhead run size, based on sport catch and hatchery returns, for 1979 through 1989 ranged from 759 steelhead in 1983 to 9,019 fish in 1986 (Tables 2, 4, 5, and 7).

Time of migration

Entry time for returning adults is generally April through October, peaking in June and July. Summer steelhead return to the Cowlitz Hatchery primarily (approximately 70%) in October and November. The freshwater life history of summer steelhead in the Cowlitz River is illustrated in Figure 1.

Harvest

Ocean catches of Cowlitz River steelhead are unknown.

The Columbia River sport fishery catches large numbers of steelhead and although the number of Cowlitz River steelhead caught is not known, some Cowlitz fish are probably part of the harvest.

Based on estimates from punchcard returns, sport catch within the Cowlitz Subbasin from 1980 through 1990 ranged from 531 fish in 1983 to 6,313 fish in 1986 (Tables 3 and 6).

Treaty harvest does not occur in the Cowlitz Subbasin.

Spawning period

Summer steelhead spawning within the subbasin occurs from December through May, peaking in February and March (Howell et al. 1985). Cowlitz hatchery stock are spawned at the Cowlitz Hatchery from mid-December through February.

Spawning area

Spawning occurs at the Cowlitz Hatchery. Steelhead which spawn naturally within the subbasin are restricted to the Cowlitz River below **Mayfield** Dam and also within portions of the Toutle River.

Fecundity

Fecundity for Cowlitz hatchery-stock summer steelhead ranged from 3,888 eggs per female based on 17 females spawned in 1985 to 4,999 eggs per female based on 46 females spawned in 1986 Table 15.

Age Composition

Age composition of summer steelhead returning to the Cowlitz River in 1979, 1980 and 1981 showed wild fish constituted 9.7 percent, 5.4 percent and 10.5 percent respectively. Wild fish in this case indicates fish with more than 1 year of freshwater growth as determined by scale analysis. Wild Cowlitz summer steelhead are progeny of hatchery origin or steelhead strays which successfully spawned in the subbasin. Age structure for summer steelhead collected in the Cowlitz

River in 1979, 1980 and 1981 averaged 5.4% for 1-ocean fish, 80.2% for **2-ocean** fish, 11.9% for **3-ocean** fish, and 1.6% were repeat spawners (Tables 9 and 10).

Size

Fork lengths from returning Cowlitz summer steelhead in 1979 and 1981 was 62.8 cm for 1-ocean fish, 73.2 cm for **2-ocean**, 84.0 for **3-ocean**, and 96.0 cm for repeat spawners (Howell et al. 1985). Wild steelhead were not included in the analysis. Lengths by individual age class, including wild fish, for the Cowlitz and Toutle rivers is presented in Tables 13 and 14, respectively.

Sex ratio

Data obtained from 153 fish collected from the Cowlitz River between 1979 and 1981 were 50.9 percent female (Table 6). In addition, 352 fish collected from the Toutle River in 1981, 1989, and 1990 were 65.9 percent female (Tables 11 and 12).

Survival Rate

Return rates for smolts planted to adult hatchery rack returns for the period 1980 through 1987 averaged 3.07 (Table 8).

JUVENILE LIFE HISTORY

Egg

No data is available on egg production or egg to smolt survival.

Emergence

Eggs are incubated and hatched in hatchery environment.

Juvenile rearing

Cowlitz smolts are reared approximately one year to an average size ranging between 65-114 grams each (4-7 fish per Round) at time of release.

Hatchery Releases

Summer steelhead were introduced into the Cowlitz **Subbasin** in 1968 in an attempt to provide a sport fishery and enough escapement to maintain hatchery production. **Skamania** summer steelhead were originally released into the **subbasin** (1968) but starting in 1972 broodstock were developed from Cowlitz River steelhead. The successful establishment of a summer steelhead run has led to continued releases of hatchery smolts into the subbasin. Tables 16 and 17 outlines smolt releases into the Cowlitz **Subbasin** for the period 1980 through 1990.

Straying

A terminal fishery on the **Cowlitz** in 1980 captured steelhead which strayed into the Cowlitz River. This data is presented in Table 18.

BIOCHEMICAL-GENETIC CHARACTERISTICS

The only data on genetic features of Cowlitz summer steelhead is from Thorgaard (1977) who determined that 83.3 % of the Cowlitz stock had 58 chromosomes and 16.7% had 59 chromosomes. These values correspond with the Skamania stock summer steelhead, from which-the Cowlitz stock was derived, that also have 58 chromosomes (Howell et al. 1985).

DISEASES

Cowlitz summer steelhead have suffered repeated infestations of the myxosporidian Ceratomyxa shasta. In an effort to control and eradicate this parasite, an ozone water treatment system was installed and preliminary indications on the success of the ozone system are positive. Disease history for the Cowlitz Hatchery is presented in Table 19.

REFERENCES

The references for this section appear at the end of the following hatchery produced winter steelhead section.

COWLITZ RIVER SUBBASIN

Naturally Produced Winter Steelhead

GEOGRAPHIC LOCATION

The Cowlitz River is located in southwest Washington, within Lewis and Cowlitz Counties. From its headwaters in the Cascade Mountains the Cowlitz River flows southwesterly, joining the Columbia River at river mile (RM) 68. Total drainage encompasses approximately 2,480 square miles and includes the Toutle River, with a drainage of 512 square miles entering the Cowlitz at RM 20, and the Coweeman River, with a drainage of 127 square miles joining the Cowlitz at RM 1.7.

ORIGIN

Cowlitz winter steelhead are indigenous although interbreeding has probably occurred with Cowlitz hatchery-stock steelhead.

The Toutle and Coweeman rivers each contain their own native winter steelhead stocks. The Toutle stock has probably been genetically influenced by Chambers Creek, Elokomina and Cowlitz hatchery-stocks. The Coweeman stock has probably incurred some interbreeding with the introduced Chambers Creek, Cowlitz and Elokomina hatchery fish.

DISTRIBUTION

Table 1 lists estimated amount of rearing/spawning habitat, by quality, for Cowlitz Subbasin steelhead based on estimates from the Northwest Power Planning Council.

Tables 2, 3, and 4 list estimated amount of rearing/spawning habitat and potential smolt production for the Cowlitz River, Toutle River and Coweeman River based on Washington Department of Wildlife gradient, area and flow methodology. Figures 1 and 2 illustrate the probable spawning areas of steelhead in the Cowlitz subbasin (Howell et al. 1985).

Distribution of winter steelhead is throughout the subbasin including the Toutle River, Coweeman River and the mainstem Cowlitz. Within the Cowlitz River, winter steelhead are found primarily below Mayfield and Mossyrock dams. These dams block anadromous fish migrations into the upper Cowlitz River and eliminate more than 50 percent of winter steelhead spawning and rearing habitat. Within the Toutle River little is known on exact distribution of winter steelhead although they were probably distributed throughout the watershed. The 1980 eruption of Mount St. Helens greatly altered the habitat on the Toutle River. Steelhead in the Coweeman River are distributed throughout the watershed including the mainstem Coweeman, Goble Creek and other tributaries. The volcanic eruption had little impact on the Coweeman River.

PRODUCTION

Production Facilities

The Cowlitz Trout Hatchery located on the Cowlitz River at RM 42 is the only hatchery producing steelhead (summer and winter) in the subbasin.

Production Summary

No data is available on wild smolt production. Natural production occurs in both the mainstem Cowlitz and throughout many tributaries. Production is limited on the Cowlitz River by the loss of

upstream spawning/rearing habitat. Production on the Toutle River is unknown but was severely reduced during the early 1980's by the eruption of Mount St. Helens. Production within the Coweeman watershed is unknown.

ADULT LIFE HISTORY

Run Size and Escapement

Historical estimates point to large runs of winter steelhead in the Cowlitz River. Over 20,000 wild winter steelhead were estimated to return **annually** to the Cowlitz River (Meigs, no date; Moore and Clark, no date). Current wild steelhead returns in the Cowlitz River are small. For 1977-78, 1978-79 and 1982-84, wild fish contributed an average of 1.7 percent of adult returns (Tables 5 and 7). Applying the 1.7 percent wild run estimate for 1977 through 1979 and 1985 through 1989, yields 309 wild fish annually. However, large numbers of hatchery-stock steelhead spawn in the Cowlitz River. In 1985, Tipping (1985) estimated Cowlitz River spawning escapement (hatchery and wild fish) at 5,703 fish.

No data is available on historical run size of Toutle River winter steelhead. The eruption of Mount St. Helens in 1980 destroyed a significant amount of Toutle spawning and rearing habitat which reduced production and run size. After the eruption, returning Toutle River steelhead were observed straying to other streams such as the Kalama River (**Leider** 1989). Toutle River habitat has improved: Lucas (1986 and **1987**), and Lucas and Pointer (1987) estimated that between 1985 and 1989 an average of 2,743 winter steelhead escaped annually to spawn (Tables 8 and 10).

Winter steelhead escapement to the Coweeman River was estimated at 889 fish, 1,088 fish, and 392 fish in 1987, 1988, and 1989, respectively (Lucas and Pointer 1987). Based on 1989 punchcard data, 38.6 percent of the Coweeman River winter steelhead sport catch were wild fish.

Time of migration

Entry time into the **Cowlitz** River for returning wild adults is generally from late November through early May, peaking in March and April. Figure 3 illustrates the freshwater life history of winter steelhead in the **Cowlitz** River.

Toutle River winter steelhead migration is January through May with peak movement in March and April.

Coweeman River winter steelhead migration period is believed to be January through May, peaking in **March**.

Harvest

Ocean catches of **Cowlitz Subbasin** (Cowlitz, Toutle and Coweeman rivers) steelhead are unknown.

The Columbia River sport fishery catch large numbers of steelhead. An estimated 6.2 percent of returning **Cowlitz** steelhead are harvested in the Columbia River.

Sport harvest of winter steelhead within **the** Cowlitz River is primarily hatchery fish. Based on winter steelhead sampled in 1977-1978, 1978-1979 and 1983-1984 wild steelhead contributed 1.2 percent, 1.3 percent, and 1.5 percent respectively, of the total sport catch (Table 6).

Toutle River sport harvest was suspended during the early 1980's with a reopening of sport fishing in 1983. New restrictions were issued which included limiting fishing to the South Fork only, reducing the fishing season and a one-fish catch limit. Based on punchcard estimates, annual sport

harvest for the period 1987 through 1990 averaged 223 steelhead (Table 9). Based on punchcard estimates, annual sport catch within the Cowlitz River from 1986 through 1989 averaged 241 fish. Regulations implemented in 1989 restrict harvest in the Cowlitz River to fin-clipped hatchery fish only, so that all wild steelhead must be released.

Spawning period

Winter steelhead spawn in the Cowlitz River from December through June with peak spawning occurring April through June.

Toutle River winter steelhead spawn from March through June.

Coweeman River winter steelhead spawn from March through June.

Spawning area

Due to the two dams which block anadromous fish migrations, spawning is restricted to the lower **mainstem** Cowlitz River including tributaries.

All spawning areas on the Toutle River were reduced significantly by the eruption of Mount St. Helens although the lower **mainstem** river suffered the greatest damage. Spawning currently occurs in the North and South Fork Toutle and many tributaries including the Green River and Alder Creek.

Wild steelhead spawn throughout the **mainstem** Coweeman River and Goble Creek, plus the lower sections of Mulholland and Baird creeks.

Fecundity

The availability of fecundity data for Cowlitz **Subbasin** wild winter steelhead is meager. Two separate spawnings of Toutle River fish showed the following: 49 females live-spawned in 1988 with a mean length of 70.4 cm yielded 3,900 eggs per female; and in 1982, **Schuck** and Kurose live-spawned 26 steelhead with a mean fecundity of 2,251 eggs per female. It is important to note that live-spawning does not strip all eggs from a fish, thus it is not an exact measure of fecundity.

Age Composition

Age composition of wild winter steelhead returning to the Cowlitz River in 1977-1978, 1978-1979 and 1983-1984 averaged 62.2 percent **2-ocean** fish, 32.2 percent **3-ocean** fish, 2.0 percent **4-ocean** fish and 3.3 percent repeat spawners (Table 13).

Age structure of wild steelhead returning to the Toutle River in 1981, 1989 and 1990 were predominately **2-ocean** fish (Table 14).

No data is available for the Coweeman River.

Fork Lengths

Data is limited on lengths of Cowlitz River wild steelhead. From wild winter steelhead collected in 1977-1978, 1978-1979 and 1983-1984 mean lengths averaged 69.4 cm for **2-ocean** fish, 81.3 cm for **3-ocean** fish, 86.0 cm for **4-ocean** fish and 74.5 cm for repeat spawners (Table 17).

Lengths obtained from wild winter steelhead trapped in the South Fork Toutle River in 1981, 1989 and 1990 averaged 44.7 cm for 1-ocean fish, 66.8 cm for **2-ocean** fish, 80.1 cm for **3-ocean** fish and 81.5 cm for repeat spawners (Table 18). No data is available for Coweeman River steelhead.

Sex ratio

Percent females for wild Cowlitz River winter steelhead in the 1977-1978, 1978-1979 and 1983-1984 run years were 35.7 percent, 36.0 percent and 41.1 percent respectively (Table 15).

Percent females for Toutle River steelhead for the run years 1980-1981, 1988-1989 and 1989-1990 were 50 percent, 64.7 percent and 90.6 percent, respectively (Table 16). No data is available for the Coweeman River.

Survival Rate

No data is available on survival rates for Cowlitz **Subbasin** wild winter steelhead.

JUVENILE LIFE HISTORY

Egg

No data is available on egg production or egg-to-smolt survival for Cowlitz **Subbasin** wild steelhead.

Emergence

For the Cowlitz River, emergence occurs from February through July, peaking in May and June.

Juvenile rearing:

Cowlitz River smolts, based on a three year mean, showed that 90.0 percent resided for two years while 9.1 percent resided for three years, prior to emigrating to saltwater (Tipping 1984; Tipping et al. 1979).

Toutle River smolts emigrated at the ratio of 86.5 percent two year old fish and 13.5 percent three year old fish (**Schuck and Kruse** 1982).

Juvenile Cowlitz **Subbasin** steelhead emigrate in April and May, generally peaking in early May (Table 12).

Straying

No data are available on Cowlitz **Subbasin** steelhead.

BIOCHEMICAL-GENETIC CHARACTERISTICS

No data is available on Cowlitz **Subbasin** wild **steelhead**.

DISEASES

No data is available on diseases which effect wild steelhead. In the **mainstem** Cowlitz, the pathogen Ceratomyxa ~~Elasta~~ **Elasta** which is prevalent in this drainage, may affect wild stocks. y f o r hatchery winter steelhead is listed in the **Cowlitz** River winter steelhead (hatchery) report.

COWLITZ RIVER SUBBASIN

Hatchery Produced Winter Steelhead

GEOGRAPHIC LOCATION

The Cowlitz River is located in southwest Washington, within Lewis and Cowlitz Counties. From its headwaters in the Cascade Mountains the Cowlitz River flows southwesterly, joining the Columbia River at river mile (RM) 68. Total drainage encompasses approximately 2,480 square miles and includes the Toutle River, with a drainage of 512 square miles entering the Cowlitz at RM 20, and the **Cowweman** River, with a drainage of 127 square miles entering the Cowlitz at RM 1.7.

ORIGIN

The Cowlitz winter stock was developed in the late 1960's at the Cowlitz Hatchery. Original broodstock were native Cowlitz River winter steelhead and Chambers Creek hatchery stock steelhead.

DISTRIBUTION

Cowlitz River steelhead are primarily released into the Cowlitz Subbasin. Since 1970 the following streams, all tributaries of the Lower Columbia, have received occasional plants of **Cowlitz** stock winter steelhead: Grays River (RM 20.8); Elokomina River (RM 39.1); **Kalama** River (RM 73.1); Washougal River (RM 120.7); Lewis River (RM 87.0); **Skamokawa** Creek (RM 33.2); Abernathy Creek (RM 54.3); Germany Creek (RM 56.2); Salmon Creek (RM 87.5), and the mainstem Lower Columbia River.

PRODUCTION

Production Facilities

The Cowlitz Trout Hatchery, located on the Cowlitz River at RM 42, is the only facility producing steelhead (summer and winter) in the subbasin. The hatchery consists of 104 hatching troughs, eight 10 ft x 100 ft raceways, twenty-four 20 ft x 90 ft raceways, and four five acre rearing ponds. Water is supplied by nine wells and pumped river water (river water supplies over 90 percent of the total water used). Well water is used for egg incubation and fry rearing. Ceratomyxa Shasta, a prevalent fish pathogen which has caused severe fish losses at Cowlitz Hatchery, has resulted in the installation of an ozone water treatment system to disinfect up to 20 cfs of the hatchery water supply.

Production Summary

Cowlitz Hatchery annually produces approximately 1 million steelhead smolts (summer and winter) with a winter steelhead production goal of 750,000 fish. Production from 1980-1986 averaged 485,159 smolts while production in 1989, 1990 and 1991 was 815,224 and 823,176 and 769,415, respectively. The fish pathogen C. Shasta, transmitted in river water, but not infective directly from fish to fish, has limited fish production so severely that an ozone water treatment system was installed at the hatchery to eradicate this parasite.

Three problems limit hatchery production: poor water quality, (water is supplied mainly from the Cowlitz River which tends to carry a high number of pathogens, has low winter water temperatures and high sediment load); disease, (numerous pathogens infect **Cowlitz** fish with Ceratomyxa shasta and Infectious Hematopoietic Necrosis (**IHN**) responsible for the greatest mortality); and bird

predation, large numbers and species of birds which continually prey upon hatchery fish (Jansen 1991).

ADULT LIFE HISTORY

Run Size and Escapement

Steelhead run size, based on sport catch, escapement, and hatchery returns, from 1979 through 1989 ranged 4,004 steelhead in 1983-1984 to 25,904 fish in 1986-1987 (Tables 1 and 3). Winter steelhead returning to the **Cowlitz** River are predominately hatchery fish with Cowlitz hatchery-stock steelhead estimated to be 98.3 percent of the returns for 1977-1979 and 1985-1989. With average returns for these periods estimated at 18,214 fish, hatchery fish totaled 17,904 steelhead (Subbasin Plan 1990).

Returns to the Coweeman River from 1986 through 1990 ranged from 1,795 fish in 1988-1989 to 2,227 fish in **1986-1987** (Table 5).

Time of migration

Entry time into the Cowlitz River for returning adults is **generally** from late November through early May, peaking in December and January.

Harvest

Ocean catch of Cowlitz River steelhead is unknown.

The Columbia River sport fishery catch large numbers of steelhead. An estimated 6.2 percent of returning Cowlitz steelhead are harvested in the Columbia River.

Sport harvest of winter steelhead from 1977 through 1979 within the Cowlitz **Subbasin** averaged 18,518 fish with 75.1 percent of the catch occurring in the Cowlitz River, 21.3 percent in the Toutle River, and 3.6 percent in the Coweeman River. For 1985 through 1989, Cowlitz **Subbasin** harvest **averaged** 13,942 fish with 92.9 percent occurring in the Cowlitz River, 1.8 percent in the Toutle River^A and 5.2 percent in the Coweeman River (Tables 2 and 4). The Cowlitz River is open year around with a two-fish catch limit. Fish entering the Cowlitz Trout Hatchery or the barrier dam separator are recycled back to the river to increase sport harvest opportunity. After the eruption of Mount St. Helens in 1980 the Toutle River was closed until 1983 when only the South Fork was open with a one-fish catch limit. The Coweeman River has recently (1989) been restricted to a wild steelhead release stream so that only fin-clipped hatchery **fish** may be retained by anglers.

Spawning period

Winter **steelhead** spawning at Cowlitz Trout Hatchery occurs primarily from mid-December through February although spawning has taken place as late as May.

^A**Toutle** River harvest closed 1980 through 1983 due to eruption of Mount St. Helens.

Spawning area

Spawning occurs at the **Cowlitz** Hatchery, the **mainstem** Cowlitz River and most tributary streams.

Fecundity

Fecundity for Cowlitz hatchery-stock ranged from a low of 3,865 eggs per female based on 40 females spawned in 1981-1982, to a high of 6,718 eggs per female based on 21 females spawned in

1984-1985 (Table 6 and 11).

Age Composition

Age composition of hatchery winter steelhead returning to the Cowlitz River in 1977-1978, 1978-1979 and 1983-1984 were 0.3 percent 1-ocean jacks, 63.5 percent **2-ocean** fish, 32.8 percent 3-ocean fish, 0.5 percent **4-ocean** fish, and 2.9 percent repeat spawners (Table 7).

Fork Lengths

Fork lengths from returning Cowlitz winter steelhead in 1977-1978, 1978-1979 and 1983-1984 ranged from 48.0 cm for a 1-ocean jack males to 99.0 cm for a five year old repeat spawner. Individual lengths by age class is presented in Table 9 and 10.

Sex ratio

Data obtained from Cowlitz winter steelhead hatchery returns showed male:female sex ratios in 1977-1978, 1978-1979 and 1983-1984 were 1.04, 1.07 and 1.78, respectively (Tipping 1984; 1991) (Table 8).

Survival Rate

Based on five return years, 1975 through 1980, the smolt-adult return rate for planted smolts returning to the Cowlitz Hatchery ranged from 2.1 percent return in 1978-1979 to 4.8 percent in 1977-1978 (Table 12).

JUVENILE LIFE HISTORY

Egg

Two years of data from release years 1988 and 1989 showed egg to smolt survival of 38.2 percent and 37.0 percent, respectively. These low survival rates are due in large part to the fish pathogen *Ceratomyxa shasta*.

Juvenile rearing

Cowlitz smolts are reared approximately one year to a size between 65-114 grams each (4-7 fish per pound) at time of release.

Juvenile steelhead are released in April and May.

Hatchery Releases

Winter steelhead were introduced into the Cowlitz **Subbasin** in 1933.. Various stocks have been released into the Cowlitz River (Chambers Creek and Beaver Creek), but in 1967 fish planted in the **Cowlitz** were almost exclusively Cowlitz Stock (Tables 13 and 14). Under a mitigation agreement between Washington Department of Wildlife and Tacoma City Light, the goal of hatchery production is the annual release of 750,000 winter steelhead smolts, which would provide an adult return of approximately 22,000 fish and a sport catch of 15,400 fish.

In addition to steelhead released into the Cowlitz River, winter steelhead are also released into the Toutle and Coweeman rivers in an attempt to increase sport catch. Since 1970, several stocks have been released into these rivers, (Chambers Creek, Elokomin and **Cowlitz**), with plants exceeding 100,000 **fish** in the Toutle in the 1970's. **Toutle** River smolt and fingerling releases were reduced to

under **35,000** from 1981 through 1987. Current plans do not call for hatchery plants in the Toutle River. The objective of fishery managers is to protect and increase wild Toutle River steelhead. From 1970 through 1988, the **Coweeman** River averaged 49,500 smolts released annually. Current releases are anticipated to be approximately 40,000 fish.

Straying

No data are available on Cowlitz steelhead.

BIOCHEMICAL-GENETIC CHARACTERISTICS

Milner et al. (1980) did an electrophoretic profile of Cowlitz winter steelhead along with other Columbia River stocks to examine the feasibility of using biochemical genetic variation for estimating composition of mixed-stock fisheries. They concluded that sufficient genetic differentiation existed to do so. **Schreck** et al. (1986) looked at stock identification of various Columbia River steelhead, including Cowlitz fish, using cluster analysis of meristic and electrophoretic features and concluded geographical proximal stocks tend to be similar to each other (Subbasin Plan 1990). Thorgaard (1977) estimated 34.5 percent of Cowlitz winter steelhead have 58 chromosomes, 55.2 percent have 59 chromosomes, and 10.3 percent have 60 chromosomes. These results were expected since the hatchery-stock was derived from native Cowlitz stock, which is believed to have 58 chromosomes, and Chambers Creek hatchery -stock with 45.5 percent having 59 chromosomes and 54.5 percent having 60 chromosomes.

DISEASES

Cowlitz winter steelhead have suffered repeated infestations of the myxosporidian **Ceratomyxa shasta**. effort to control and eradicate this parasite, an ozone water treatment system was installed in 1991. Disease history for the Cowlitz Hatchery is presented in Table 17.

KALAMA SUBBASIN

Spring Chinook

GEOGRAPHIC LOCATION

The Kalama **subbasin** begins on the southwest slope of Mount St. Helens and flows 44.5 miles west-southwest to enter the Columbia River at River Mile (**RM**) 73. Drainage is about 205 square miles and although the headwaters begin in **Skamania** County, the majority of the **subbasin** is in Cowlitz County. There are three facilities that have reared chinook including **Gobar** Pond, located about four miles up the Kalama tributary of **Gobar** Creek. The Lower Kalama Hatchery at RM 4 and Kalama Falls Hatchery at RM 10 also rear spring chinook.

ORIGIN

Historically, few spring chinook were found in the **subbasin** (**WDF** 1951). Spring chinook were established at Kalama Falls Hatchery after its completion in 1959. Brood stock for the Kalama hatchery programs originated from a variety of sources including Eagle Creek, Willamette, Cowlitz and Little White Salmon (Howell et al. 1985). Current brood stock source is from rack returns.

DISTRIBUTION

Spring chinook are distributed primarily below Kalama Falls Hatchery although some have been passed upstream in large return years. Most of the spawning in the Kalama River occurs between the upper Kalama Falls (RM 36.8) and the Kalama Falls Hatchery (**RM** 10.5).

PRODUCTION

By the 1950's only remnant populations (escapements fewer than 100 fish) existed in the Kalama River. Natural spawning population estimates of spring chinook in the Kalama River between 1975 through 1983 averaged 757 fish (Howell et al. 1985). Hatchery production is the dominant component in the Kalama River although some natural production also occurs.

Tables 1 and 2 describe the amount of spawning and rearing habitat by quality, available in the Kalama River. This data was derived from the Presence/Absence database of Northwest Power Planning Council (1991).

The Northwest Power Planning Council's model estimated a **subbasin** capacity of 111,192 smolts below Kalama Falls plus another 465,160 smolts above Kalama Falls. However, the small historic run sizes might suggest a habitat constraint or degradation.

The Kalama River spring chinook natural spawn escapement from 1977-1984 brood years averaged 826 with a low return of 30 for the 1981 brood and a peak of 2,595 for the 1978 brood. Kalama River natural spawn escapement by age and brood year are presented in Table 3.

Kalama hatchery spring chinook returns from 1977-1984 brood years averaged 1,423 with a low return of 149 for the 1981 brood and a peak of 3,616 for the 1978 brood. Kalama hatchery returns by age and brood are presented in Table 4.

Kalama River tributary sport catch estimates from 1977-1984 brood years averaged 1,149 with a low of 279 for the 1981 brood and a peak of 2,587 for the 1978 brood. Kalama River tributary sport catches by age and brood year are presented in Table 5.

The **Kalama** River spring chinook total returns from 1977-1984 brood years averaged 3,397 with a low of 458 for the 1981 brood and a peak of 8,798 for the 1978 brood. Kalama River total returns by age and brood year are presented in Table 6.

ADULT LIFE HISTORY

Run size, catch and escapement

Ocean commercial and recreational fisheries from Alaska to Washington, in addition to Columbia River gill net and sport fisheries, all harvest a portion of the Kalama River origin spring chinook. Ocean and Columbia River fisheries on Kalama spring chinook were estimated to account for 45 percent of production in the System Planning Model. Relatively little harvest occurs in the ocean while Columbia River commercial and sport fisheries comprise most of the harvest. **Subbasin** sport harvest rate on adults was 33 percent and 37 percent on jacks (**WDW**, 1990). Columbia River sport and commercial fisheries are managed to insure attainment of hatchery egg-take requirements.

Strays from other lower river hatcheries to the Kalama River are relatively uncommon. Table 7 lists the coded wire tags recovered within the Kalama **subbasin** which originated outside the Kalama subbasin. Kalama River hatchery spring chinook releases have been generally untagged.

Time of Migration

Adult time of return generally ranges from March through July.

Spawning Period

Spawning extends from late August to early October with peak activity in September.

Spawning Areas

Most of the spawning is spread out in the area between the upper Kalama falls and the Kalama Falls Hatchery, a distance of approximately 26 miles.

Age Composition

Age ranges from two-year-old mini-jacks to six-year-old adults. Four-year-old's and five-year-old's usually dominate the age classes. Total age composition data is summarized in Tables 3 and 4. Table 8 lists the age composition percentages by brood year for spring chinook returning to the Kalama River spawning grounds. Table 9 lists the age composition percentages by brood year for spring chinook returning to the Kalama River hatcheries. Table 10 lists the age composition percentage by brood year for spring chinook caught in the Kalama River sport fishery.

Sex Ratio

The percent females by age class (freshwater/ocean) for spring chinook returning to the Kalama Falls Hatchery is available in Table 11. Kalama River natural spawn percent females data is unavailable.

The mean fork length by brood year, sex, and **freshwater.ocean** rearing ages of Kalama Falls Hatchery returns from 1982-1987 brood years are available in Tables 12 and 13. Kalama River natural spawn mean fork length data is unavailable.

Fecundity

Fecundity of spring chinook spawned from 1977 through 1986 averaged 4,491 (WDW, 1990).

JUVENILE LIFE HISTORY

Time of Emergence

Emergence times were estimated to be November through March for naturally spawning fry, depending on time of egg deposition and water temperatures.

Time, age and size at migration

Hatchery release information for the Kalama **subbasin** by brood year is presented in Table 14. Length data of natural spring chinook smolts from the Kalama River is unavailable. The number of natural juvenile spring chinook salmon that migrate from the Kalama River is also unavailable.

Survival Rate

Smolt-to-adult survival averaged 3.05 percent for the 1971 and 1974 brood years and ranged from 0.02 percent to 5.16 percent. Smolt-to-adult returns to the Kalama for the 1975 through 1982 broods averaged 1.73 percent. Egg-to-fry survival averaged 90.6 percent for 1982 through 1986 broods while fry-to-smolt survival averaged 84.0 percent, resulting in an egg-to-smolt survival of 76.1 percent (WDW, 1990).

Seidel and Mathews (1977) found September released fingerlings (18 grams) had a minimum of 0.47 percent survival while yearlings (65 g) had a minimum of 2.70 percent survival.

BIOCHEMICAL-GENETIC CHARACTERISTICS

Milner et al. (1983) measured the genetic distances between Cowlitz and Kalama Falls spring chinook. The within group variation was one of the lowest for 17 different stock group comparisons, indicating a relatively high degree of genetic homogeneity. Schreck et al. (1986) compared their samples to those of Milner et al. (1983) in order to determine if there were any genetic changes in stock between sampling dates. The results indicated a statistically significant difference in isozyme frequencies for one enzyme system between the current and historical profiles for both the Cowlitz and Kalama Falls samples.

DISEASE

Bacteria and parasitic diseases found in the Kalama hatcheries are listed in Table 15 (WDF Salmon Culture, Olympia).

REFERENCES

The references for this section appear at the end of the following fall chinook section.

Bacteria	Kalama Falls	<i>Yersinia ruckeri</i> (Enteric Redmouth)
Bacteria	Kalama Falls	<i>Renibacterium salmoninarium</i> (Bacterial Kidney Disease)
Parasite	Kalama Falls	Various Ectoparasites, Endoparasites and Myxosporidians
Parasite	Kalama Falls	<i>Ichthyophthirius multifiliis</i> (Ichthyophthirius)

Disease history only represents pathogens isolated at the hatchery, and not necessarily a disease outbreak.

KALAMA SUBBASIN

Fall Chinook

GEOGRAPHIC LOCATION

The Kalama **subbasin** begins on the southwest slope of Mount St. Helens and flows 44.5 miles west-southwest to enter the Columbia River at River Mile (**RM**) 73. Drainage is about 205 square miles and headwaters begin in Skamania County, although the majority of **the basin** is in Cowlitz County. There are two hatcheries in the **subbasin** that produce fall chinook: the Lower Kalama Hatchery at RM 4; and Kalama Falls Hatchery at RM 10.

ORIGIN

Fall chinook have been planted into the Kalama **subbasin** since 1895 when the Lower Kalama Hatchery was completed. Kalama Falls Hatchery was completed in 1959. Brood stock for the two hatcheries are taken from rack returns.

The two salmon hatcheries on the Kalama were used as an egg-bank temporarily from 1981 through 1986 for the Lyons Ferry upriver bright stock fall chinook. That program and its returns will not be addressed herein due to its temporary status.

DISTRIBUTION

The Washington Department of Fisheries (1951) estimated three-quarters of the fall chinook spawned in the lower three miles of the river below hatchery racks but upstream from tidewater. Both hatcheries primarily collect brood stock by installing a temporary rack upstream from tidewater near the **Modrow** Bridge at RM 3. Surplus fall chinook are passed upstream from the rack to spawn naturally. Fall chinook upstream migration is terminated at Kalama Falls Salmon Hatchery unless surplus fish are released upstream from the hatchery. Currently, Kalama River fall chinook spawning ground index counts are conducted annually from Italian Creek downstream to the I-5 Bridge, a distance of about 9 miles.

PRODUCTION

Historically, fall chinook in the **subbasin** were abundant. Run size prior to the hatchery plants is difficult to determine because hatchery plants began in 1895. The Lower Kalama Salmon Hatchery began operation in 1895 when 4 million eggs were taken from a fish rack about one mile upstream from the confluence with the Columbia River. The Washington Department of Fisheries (1951) estimated Kalama fall chinook escapement of 20,000 fish. Hatchery production is currently the dominant component in the Kalama River although some natural production also occurs.

Table 1 describes the amount of spawning and rearing habitat, by quality, available in the Kalama River. This data was derived from the Presence/Absence database of Northwest Power Planning Council, 1991.

Fall chinook natural production of juveniles using the Northwest Power Planning Council's model was estimated at 162,200 and 428,670 fingerlings above and below Kalama Falls Hatchery, respectively.

The Kalama River tule fall chinook natural spawn escapement **from** 1978-1984 brood years averaged 8,349 with a low return of 971 for the 1981 brood and a peak of 40,831 for the 1984 brood. Kalama River tule fall chinook natural spawn escapement by age and brood year are presented in Table 2.

Lower Kalama **and** Kalama Falls Hatcheries combined tule fall chinook returns from 1979-1984 brood years averaged 5,931 with a low return of 3,554 for the 1982 brood and a peak of 8,738 for the 1984 brood. Kalama River hatcheries tule fall chinook return by age and brood year are presented in Table 3.

Kalama River tributary sport catch estimates between 1977 through 1986 averaged **641 adults and 224 jacks** for a combined harvest rate of 9.5 percent (**WDW**, 1990). However, specific age and brood year analysis for Kalama River sport catch is unavailable.

ADULT LIFE HISTORY

Run size, catch and escapement

Ocean commercial and recreational fisheries from Alaska to Washington, in addition to Columbia River gill net and sport fisheries all harvest a portion of the Kalama River origin fall chinook. During 1983 through 1987, the overall harvest rate was 81 percent (**WDW**, 1990). Columbia River sport and commercial fisheries are managed to insure attainment of hatchery egg-take requirements.

Strays from other lower river hatcheries and natural production are not unusual. Table 4 lists Kalama Hatchery origin fall chinook stray coded wire tag recoveries beginning with the 1978 brood through to the 1988 brood and Table 5 lists the coded wire tags recovered within the Kalama **subbasin** which originated outside the Kalama subbasin.

Time of Migration

Upstream migration begins in early August and continues through September. Depending partly on early fall rains and tributary migration distances, recruitment to most hatchery collection sites is usually greatest during the middle of September.

Spawning Period

Spawning at the Kalama facilities occurs from late September into November and peaks in early to mid-October. Natural spawning generally occurs concurrently with the spawning of the hatchery run.

Spawning Areas

Kalama River tule fall chinook spawning ground peak index counts are conducted annually between Italian Creek and the I-5 Bridge. Fall chinook are not found upstream from Kalama Falls Hatchery **unless** they are put upstream.

Age Composition

Age ranges from two-year-old jacks to six-year-old adults with three-year-olds or four-year-olds usually the dominate age classes. Total age composition data is summarized in Tables 2 and 3. Table 6 lists the age composition percentages by brood year and freshwater-ocean rearing for tule fall chinook returning to the Kalama River spawning grounds. Table 7 lists the age composition percentages by brood year and freshwater-ocean rearing for **tule** fall chinook returning to the Lower Kalama and Kalama Falls Hatcheries.

Sex Ratio

Female tule fall chinook comprised 47-63 percent of the natural spawners in the Kalama River between 1981-1984 brood years. The percent females by brood year and freshwater-ocean rearing ages for Kalama River natural spawners are presented in Table 8.

Female tule fall chinook comprised 36-53 percent of the fall chinook returning to the Kalama River hatcheries between 1981-1984 brood years. The percent females by brood year and freshwater-ocean rearing ages for Kalama River hatcheries return are presented in Table 9.

The mean fork length by brood year, sex, and **freshwater.ocean** rearing ages of Kalama River tule natural spawners for 1977-1985 brood years are available in Tables 10 and 11.

The mean fork length by brood year, sex, and **freshwater.rearing** ages for Kalama River hatcheries tule returns for 1978-1984 brood years are available in Tables 12 and 13.

Fecundity

Fecundity at the **Kalama** facilities averaged 4,574 during 1978-1982 (Howell et al. 1985). Fecundity at the Lower Kalama Hatchery between 1983-1990 return years excluding 1988 averaged 4,315 and ranged from a low 3,892 in 1985 to a high 5,510 in 1986. Fecundity at the Kalama Falls Hatchery between 1983-1990 return years averaged 4,731 and ranged from a low of 3,872 in 1985 to a high of 5,561 in 1989. Kalama River natural spawn and hatchery fecundity data by age and brood year are unavailable.

JUVENILE LIFE HISTORY

Time of Emergence

Emergence times were estimated to be early May for naturally spawning fry, depending on time of egg deposition and water temperatures (**Reimers** and Loeffel, 1965).

Time. age and size at migration

Some tagged hatchery releases from Kalama Falls Hatchery were recovered in the Columbia estuary as sub-yearlings in October and November. Kalama Falls Hatchery coded wire tags were recovered at Jones Beach (Columbia River Mile 47) in the Columbia River estuary during seining operations in 1977-1981 (Howell et al. 1985). Juvenile emigration peaks in June through August although some emigration occurs through December (**WDW**, 1990).

The average fork length of 1978 brood natural fall chinook smolts from the Kalama River was 40 mm. Chinook average length and ranges are based on spring 1979 seining results from the Kalama River. Length data of 1978 brood natural **fall** chinook smolts from the Kalama River is available in Table 15.

The number of natural juvenile fall chinook salmon that migrated from the Kalama River in 1989 was estimated to be between 522,312 and 964,439 fish. Population estimates were based upon comparing catch per unit effort (CPUE) on fall chinook juvenile seining on the Kalama River in 1989 with 1983-1989 North Fork Lewis wild juvenile population estimates and CPUE. Table 14 lists the number of natural fall chinook that migrated from the Kalama River in 1989.

Hatchery release information for the Kalama River **subbasin** by brood year is presented in Table 16.

Survival Rate

Results of the 1961-1963 brood fall chinook hatchery evaluation study included specific analysis of the Kalama Falls Hatchery production. The overall **catch:escapement** ratio was an average of 12.1: 1 for the three brood years and a high of **16.0:1** for the 1962 brood. In general, the 1961-1963 brood **catch:escapement** ratio was generally higher than other hatchery fall chinook (**WDF**, 1973).

Based on a 1976 brood Kalama Falls Hatchery fall chinook coded wire tags (**63-16-39**), smolt-to-ail adult survival was 1.2 percent, smolt-to-fisheries 0.9 percent, and smolt-to-Columbia River 0.4 percent (Howell et al. 1985). Performance of plants (catch plus escapement), based on marked 1978 through 1981 brood production fish averaged 0.17 percent with a range of 0.08 percent to 0.32 percent. Marked production **fish** had 0.26 percent and 0.21 percent fingerling-to-adult survival for 1977 through 1981 broods at the Lower Kalama and Kalama Falls, respectively. Fingerlings released to adult returns to the river averaged 0.19 percent for the 1975 through 1981 broods (**WDW**, 1990).

Seidel and Mathews (1977) found survival at Lower Kalama Hatchery was a minimum of 2.25 percent versus 0.74 percent for early July released large (24 grams) and small (7 g) fingerlings, respectively. September releases of large (65 g) and small (19 g) fingerlings survived at a minimum of 6.52 percent and 0.99 percent, respectively. April released yearlings (78 g) survived at a minimum of 7.95 percent. At Kalama Falls Hatchery, Seidel and Mathews (1977) found two groups of 3-gram fingerlings survived at a minimum of 0.23 percent and 0.09 percent.

Lower Kalama Hatchery egg-to-fry survival averaged 91.1 percent for 1985 through 1988 while fry-to-fingerling survival averaged 99.1 percent, resulting in an egg-to-fingerling released survival of 90.3 percent (**WDW**, 1990).

Kalama Falls Hatchery egg-to-fry survival for 1983 through 1987 broods averaged 93 percent while fry-to-planted fish survival was 94.8 percent, resulting in an egg-to-planted fish survival of 88.1 percent (**WDW**, 1990).

No survival information is available for natural fall chinook in the Kalama River.

BIOCHEMICAL-GENETIC CHARACTERISTICS

Milner et al. (1980) did an electrophoretic profile of Kalama fall chinook along with other Columbia River stocks to examine the feasibility of using biochemical genetic variation for estimating composition of mixed stock fisheries. They concluded sufficient genetic differentiation existed to do so. Schreck et al. (1986) looked at stock identification of various Columbia River fall chinook, including Kalama stock, using cluster analysis of meristic and electrophoretic features and concluded geographical proximal stocks tend to be similar.

DISEASE

Bacteria and parasitic diseases found in the Kalama River hatcheries are listed in Table 17 (**WDF** Salmon Culture, Olympia)

Table 1 **(HB-1)**. Estimated amount of rearing and spawning habitat, by quality, of the Kalama River fall chinook production area.

Distance/Area	Excellent	Good	Fair ^a	Poor ^a	Unknown	Total	Confidence
Miles (%)	00	38	33	29		18.6	
Acres (%)	00	38	32	29		133.3	

^a Ratings of fair and poor habitat quality may reflect natural physical features such as waterfall barriers, as well as degradation caused by humans.

1986	63	190	3,126				
1987	10	655					
1988	200						

Age based on scale reading analysis.

Kalama River tule fall chinook hatchery returns include Lower Kalama and Kalama Falls Hatcheries. Hatchery escapement does not include Snake River stock returns.

1987 return year - Includes 87 fish that returned to the Kalama River and spawned at Grays Hatchery.

1989 return year - Includes fall chinook that returned to the Kalama River and spawned at Lewis Hatchery.

1990 Kalama Falls return - Includes 198 adult males and 92 jacks put upstream to spawn naturally.

Time of Migration

Brood Year	Fall (subyearling)	Spring	Total
1988	522,312 - 964,439		522,312 - 964,439

Source: Pettit, R. 1990. Fall chinook juvenile test seining on the Kalama River, 1989. Columbia River Lab Progress Report, # 90-21.

Estimates based upon comparing catch per unit effort (CPUE) data collected on fall chinook juvenile seining on the Kalama River in 1989 with 1983-88 North Fork Lewis River wild juvenile fall chinook population estimates and CPUE.

Table 15 (SL). Lengths of fall chinook smolts from the Kalama River, 1979.

Location and year	No. Fish	Length ave. (mm)	Length range (mm)	Reference
Lower Kalama 1979	228	40.3	33-57	"Spring seining of 1978 brood wild fall chinook juveniles on the Kalama River, Grays River, and Skamokawa Creek". WDF memorandum from Nancy Bluestein to Don McIssac December 11, 1979.

Seven stick and/or beach seining trips were made on the Kalama River between March 28-May 17, 1979. Chinook average length and range are based on those seining results and may reflect rearing and/or outmigration size patterns.

KALAMA SUBBASIN

Coho Salmon

GEOGRAPHIC LOCATION

The Kalama **subbasin** begins on the southwest slopes of Mount St. Helens and flows 44.5 miles west-southwest to enter the Columbia River at River Mile (RM) 73. Drainage is about 205 square miles in area. Although the majority of the basin is in Cowlitz County, the headwaters begin in Skamania County. There are two hatcheries in the **subbasin** that produce **coho**. The lower Kalama Hatchery at RM 4.3 and Kalama Falls Hatchery at RM 10.

ORIGIN

A native population of **coho** was noted to be in existence in the Kalama River in 1951 by the Washington Department of Fisheries. The native population was estimated to at about 3,000 fish.

Both early returning (Type-S) and late returning (Type-N) **coho** were present (WDW, 1990). Hatchery **coho** have been planted in the **subbasin** since 1942 from the Lower Kalama Salmon Hatchery. Most existing early **coho**, Type-S, hatchery programs are considered to be linked to native Toutle River stock **coho**. Washington stations either received Toutle stock eggs or utilized local native early run **coho**. Late stock **coho**, Type-N, are informally considered synonymous with Cowlitz River stock **coho**. Late stock hatchery programs were developed utilizing Cowlitz River stock, their derivatives, or native late runs. Late **coho** used in most of the current programs are presumably a blend of all of these, although egg transfers from Cowlitz Hatchery occur most frequently (Howell et al. 1985).

DISTRIBUTION

Natural spawning occurs in most areas accessible to **coho**. In 1936 a fish ladder was built at the Kalama Falls and by 1951 **coho** were observed above the falls but numbers are unknown and distribution is probably throughout the watershed.

PRODUCTION

Typically the Lower Kalama Hatchery produces Type-S **coho** and the Kalama Falls Hatchery produces Type-N **coho**. In Washington and Oregon adult production of early and late **coho** from natural spawners is unknown except for a few instances. A factor of 10 - 15 percent might be considered reasonable for the percent of the total Columbia River **coho** production originating from naturally spawning fish (Howell et al. 1985).

Tables 1 and 2 describe the amount of spawning and rearing habitat, by quality, available in the Elochoman River. This data was derived from the Presence/Absence database of the Northwest Power Planning Council, 1991.

The number of Kalama River **coho** natural spawn escapement is unavailable. Hatchery returns by age and brood year are presented in Table 3.

Kalama River tributary sport catch estimates between 1979 - 1986 return years averaged 1,272 adult **coho**, ranging from a low of 292 in 1985 to a high of 5,525 in 1980 based on catch records. Due to low harvest rates within the subbasin, most harvest is intended to occur in the ocean and the Columbia River. The Kalama is open most of the year to general rules and regulations with some exception to fly fishing only. However, specific age and brood year analysis for Kalama River sport catch is unavailable.

ADULT LIFE HISTORY

Run size, catch and escapement

Ocean commercial and recreational fisheries off the Oregon coast are the primary-harvesters of early **coho**. The Oregon troll fishery accounts for the highest percentage of the overall catch. Most of the freshwater recreational harvest occurs in the Washington tributaries (Howell et al. 1985).

Coho returns to the Kalama hatcheries for the 1978 - 1988 brood years averaged 6,962 with a low return of 2,943 for the 1981 brood and a peak of 13,399 for the 1983 brood (Table 3). **Subbasin** harvest of **coho** averaged 441 jacks and 650 adults for 1977 through 1986. For 1981 through 1986, sport harvest rate averaged 12.5 percent (WDF, 1990).

Based on coded-wire tagged releases of 1976 - 1978 brood late **coho**, most of the harvest occurs in the Washington and Oregon ocean fisheries. Late **coho** have a more northerly migration pattern than early **coho** (WDF, 1990). This is reflected in the catch distribution where the Washington coastal catch comprised 40 percent of the total harvest compared to 20 percent for early **coho** during 1979 - 1981. Late **coho** also contribute significantly to the lower Columbia River commercial gill net fishery (Howell et al. 1985).

Strays from other lower river hatcheries are not unusual. Table 6 lists Elochoman Hatchery origin **coho** stray coded-wire tag recoveries beginning with the 1978 brood through to the 1988 brood. Table 7 lists the coded-wire tags recovered within the Elochoman **subbasin** which originated outside the Elochoman subbasin.

Harvest rates averaged 79 percent and 85 percent for Type-S and N stocks, respectively, between 1983 and 1987. Harvest of Type-S **coho** is occasionally constrained by one or more of the fall chinook stocks. Harvest of Type-N **coho** is generally not constrained by weak stocks, with hatchery escapement being the only management constraint (WDF, 1990).

Time of Migration

Early **coho** enter the Columbia River by mid-August and begin returning to the lower Columbia hatcheries in early September. In the **mainstem** Columbia River early **coho** predominate from August to mid-September. Stock composition shifts to late **coho** in late September and October. Typically, the late **coho** run begins entering freshwater in mid to late September with mid-October considered the main migratory period in the **mainstem** Columbia River (Howell et al. 1985).

Spawning Period

For Type-S **coho**, both hatchery and natural spawning occurs around late October, while for Type-N **coho** spawning will extend from late November through March, with the bulk being in December and early January (Howell et al. 1985)

Spawning Areas

Natural spawning occurs in most areas accessible to **coho** (Howell et al. 1985). Since 1936 the area above the falls was opened to spawning by construction of a fish ladder. Above the falls, Little Kalama River, Rock Creek, and Arnold Creek, along with other feeder streams, are utilized by **coho** (WDF, 1973).

Age composition

Coho return as two-year-old jacks and three-year-old adults based on hatchery personnel

designation. However, recoveries of marked production Type-N stocks indicate a 0.2 percent four-year-old adults (WDW, 1990). The age composition of the late **coho** run entering the Columbia River is not available because of incomplete escapement information and the differential trapping of adults and jacks at many collection facilities (Howell et al. 1985). Specific age composition percentage (**freshwater.ocean**) by brood year for **coho** spawning naturally and hatchery returns are unavailable.

Sex Ratio

Accounting for the differential harvest of adult males and females in the gill net fishery, the entire **coho** adult run entering the Columbia River was estimated to be 46 percent females in 1982 and 30 percent females in 1983. Hatchery adult returns were 33 percent females in 1982 and 34 percent females in 1983 (Howell et al. 1985). Specific percent females by brood year and age class (**freshwater.ocean**) for **coho** spawning naturally and hatchery returns are unavailable.

Fecundity

Fecundity of Type-S and Type-N stock **coho** from 1977 through 1986 averaged 2,759 (n= 8,526) and 2,496 (n= 5,007) eggs per female, respectively (WDW, 1990).

Kalama River natural spawn and Kalama Hatchery fecundity by age class and brood year is unavailable.

JUVENILE LIFE HISTORY

Time of Emergence

The juvenile life history for Kalama **subbasin coho** is similar to that of other stocks in the region with a spring emergence (WDW, 1990).

Time, age and size at migration

Freshwater rearing generally lasts for about 14 months. Hatchery release information for the Kalama **subbasin** by brood year is presented in Table 10. Based on coded-wire tag recovery studies by Dawley et al. (1982), arrival in the Columbia River estuary occurs soon after hatchery release (Howell et al. 1985). Length data of natural **coho** smolts from the Kalama River is unavailable. The number of natural juvenile **coho** salmon that migrate from the Kalama River is also unavailable.

Survival Rate

Smolt to adult survival rate of N stock fish averaged 4.67 percent (range: 0.56 percent to 7.71 percent) for the 1983 through 1985 brood releases while S stock survival ranged from 6.10 percent to 7.50 percent and averaged 6.80 percent for the 1973 brood year (WDW, 1990). A generalized recent year smolt to adult survival rate for **coho** was estimated to be 2.5 percent (TAC 1983, Howell et al. 1985).

BIOCHEMICAL-GENETIC CHARACTERISTICS

Data has not been compiled.

DISEASE

Bacteria and parasitic diseases found in the Kalama River Hatcheries are listed in Tables 11 and 12. (WDF Salmon Culture, Olympia).

Table 1 (HB-1). Estimated amount of rearing and spawning habitat, by quality, of the Kalama River **coho** production area.

Distance/Area	Excellent	Good	Fair ^a	Poor ^a	Unknown	Total	Confidence
Miles (%)	00	31	69	00		13.5	
Acres (%)	00	39	61	00		32.7	

^a Ratings of fair and poor habitat quality may reflect natural physical features such as waterfall barriers, as well as degradation caused by humans.

KALAMA RIVER SUBBASIN

Naturally Produced Summer Steelhead

GEOGRAPHIC LOCATION

The Kalama **subbasin** is located in southwest Washington and although the headwaters are located in Skamania County over 98 percent of the basin is in **Cowlitz** County. The Kalama River originates on the southwest slope of Mount St. Helens and flows 44.5 miles west-southwest where it enters the Columbia River, below Bonneville Dam, at river mile (**RM**) 73.1. The **subbasin** encompasses a drainage of approximately 205 square miles.

ORIGIN

The wild summer steelhead stock in the Kalama River is native, although interbreeding with introduced Skamania hatchery stocks has occurred. In addition, steelhead which abandoned the **Cowlitz** system following the eruption of Mount St. Helens in 1980, strayed into the Kalama River and spawned with native Kalama stock.

It should be noted that Chilcote et al. (1980) and Leider et al. (1984) observed known summer steelhead spawning with winter steelhead showing that Kalama River winter and summer steelhead are not entirely reproductively separate.

DISTRIBUTION

Table 1 lists rearing and spawning habitat for Kalama River steelhead based on estimates from the Northwest Power Planning Council. Department of Wildlife estimates based on gradient, area and flow methodology is presented in Table 2.

Summer steelhead are distributed throughout the **mainstem** Kalama and the North Fork, **Gobar** Creek and Wild Horse Creek. For steelhead to migrate into the upper Kalama River, fish must cross over a falls located at Kalama Falls Hatchery at RM 10. The falls has been **laddered** to allow fish passage, although tagging and visual observations indicate that steelhead are able to jump the falls in high numbers, typical jumper ratios are 1.6 fish which jump the falls to each fish using the ladder. A barrier which blocks all anadromous fish migration is a falls approximately 35 feet high at RM 36.8. Figure 1 illustrates the probable spawning areas of wild winter and summer steelhead in the Kalama, as cited by Howell et al. (1985).

PRODUCTION

Production Facilities

There are two hatcheries in the subbasin, the Lower Kalama Salmon Hatchery located at river mile 4.3 and Kalama Falls Salmon Hatchery located at river mile 10. Both hatcheries produce chinook and **coho** salmon. Steelhead are acclimated for 1-2 months at **Gobar** Pond which is located approximately four miles up **Gobar** Creek, a major tributary of the Kalama River. **Gobar** Creek is located approximately 19.5 mile upstream from the mouth of the Kalama River. **Gobar** Pond operates as a 1.5 acre dirt bottom pond about 5 or 6 feet in depth with a flow of 2.5 CFS using **Gobar** Creek water. **Gobar** Pond was constructed as a short term rearing station which would acclimate steelhead prior to release, so returns and subsequent sport catch would be enhanced.

Production Summary

Limited data is available on wild smolt production. Smolts trapped at Kalama Falls Hatchery,

located 10 miles upstream from the mouth of the Kalama River, using a traversing **fyke** net from 1978 through 1984 averaged 28,259 smolts annually (Tables 7 and 8). Steelhead production as measured by number of fish per square meter is considered moderate by Washington Department of Wildlife smolt production model. WDW smolt production is listed in Table 2. Production constraints include tributaries which are short and have high gradients, habitat degradation, lack of quality spawning gravel, and stressful summer-time high water temperatures.

ADULT LIFE HISTORY

Run Size and Escapement

Estimates of run size and escapement (hatchery and wild fish) for 1980 through 1989 is presented in Tables 3, 4 and 5. Returns of summer steelhead were exceedingly high in 1980-81 due to excessive straying of Cowlitz River steelhead caused by the eruption of Mount St. Helens in 1980.

Time of migration

Adult return time to the Kalama Falls Hatchery rack for summer steelhead is generally from March through January with peak returns of both hatchery and wild fish occurring in July (**Leider** et al. 1991).

Harvest

Ocean catch of Kalama River steelhead are unknown.

Harvest of summer steelhead within the Columbia River is estimated at approximately 6 percent based on Columbia Basin System Planning Model.

Sport harvest (hatchery and wild) from 1980 through 1990 ranged 2,540 summer steelhead in 1983-84 of 8,987 fish in 1982-83 based on permit-card harvest estimates (Table 2). Sport fishing is open year around below Kalama Falls with a two fish limit. "Wild Release" regulations were imposed on the Kalama in April 1986, limiting legal harvest to hatchery fish only.

Treaty harvest does not occur in the Kalama Subbasin.

Spawning period

Spawning occurs from December through April with hatchery fish peaking in January and wild fish peaking in February (**Leider** et al. 1991).

Spawning area

Spawning occurs in the **mainstem** Kalama River, the North Fork and many tributaries including **Gobar** and Wild Horse creeks.

Fecundity

No data is available for wild steelhead.

Age Composition

Age composition for hatchery fish is presented in Table 11.

Age composition showing percentages of wild steelhead for each age class is presented in Table 12.

Size

Mean fork lengths from steelhead sampled from **Kalama** Falls ladder is presented in Tables 14 and 15.

Sex ratio

Sex ratio for summer wild/hatchery steelhead from 1979-1984 averaged 48.2% female for hatchery fish and 51.6% female for wild fish (Table 13).

Survival Rate

No data available for wild summer steelhead. Survival based on returns of hatchery releases ranged from 0.8 percent to 3.4 percent. Smolt to adult survival rates for hatchery steelhead from 1982 through 1989 is presented in Table 6.

JUVENILE LIFE HISTORY

Egg

No data is available on egg production or egg to smolt survival.

Emergence

Wild steelhead fry emerge March through May (Subbasin Production Plan, 1990).

Juvenile rearing

Juvenile rearing lasts approximately two years prior to ocean emigration, although some juveniles emigrate after one or three years (Loch et al. 1985; Table 9). Migration generally occurs from March through June with peak migration from mid-April to mid-May. Based on summer and winter smolts captured from both the Kalama River and **Gobar** Creek smolt lengths ranged from 137.1 mm to 167.8 mm (Table 10).

Table 3b outlines smolt age composition for years 1987-1984.

Hatchery releases

In February, summer steelhead are transferred as subsmolts to **Gobar** Pond from Beaver Creek and Skamania hatcheries. Fish are released as smolts in late April or early May. Until 1988, most smolts reared in **Gobar** Pond were trucked downstream and released directly into the Kalama River while some fish were released directly into **Gobar** Creek. In 1988 and 1989, **all** fish conditioned in **Gobar** Pond were released into Kalama River reaches. Since 1990, all fish held at **Gobar** Pond have been released directly into **Gobar** Creek. Fish are generally planted as yearlings. Table 16 outlines hatchery releases into the Kalama River from 1981 through 1990.

Straying

No data on Kalama River steelhead.

BIOCHEMICAL-GENETIC CHARACTERISTICS

Milner et al. (1980) did an electrophoretic profile of Kalama summer steelhead as part of overall study of Columbia River stocks and the feasibility of using biochemical genetic variation for

estimating composition of mixed-stock fisheries. The study concluded sufficient genetic differentiation existed to do so. Since 1975 The Washington Department of Wildlife's Kalama River Research Group has worked to determine & reproductive success of hatchery and wild summer steelhead in their natural environment. In 1990 the research group, using electrophoretic examination for a specific genetic marker, found the success of hatchery fish in producing adult offspring was 12 percent that of wild fish. Further, they found 42 percent of naturally produced adult summer steelhead were offspring of hatchery spawners due to hatchery spawners outnumbering wild spawners 4.5 to 1. Based on these findings the evidence shows that the genetic integrity of wild populations may be at risk due to interbreeding between hatchery and wild stocks.

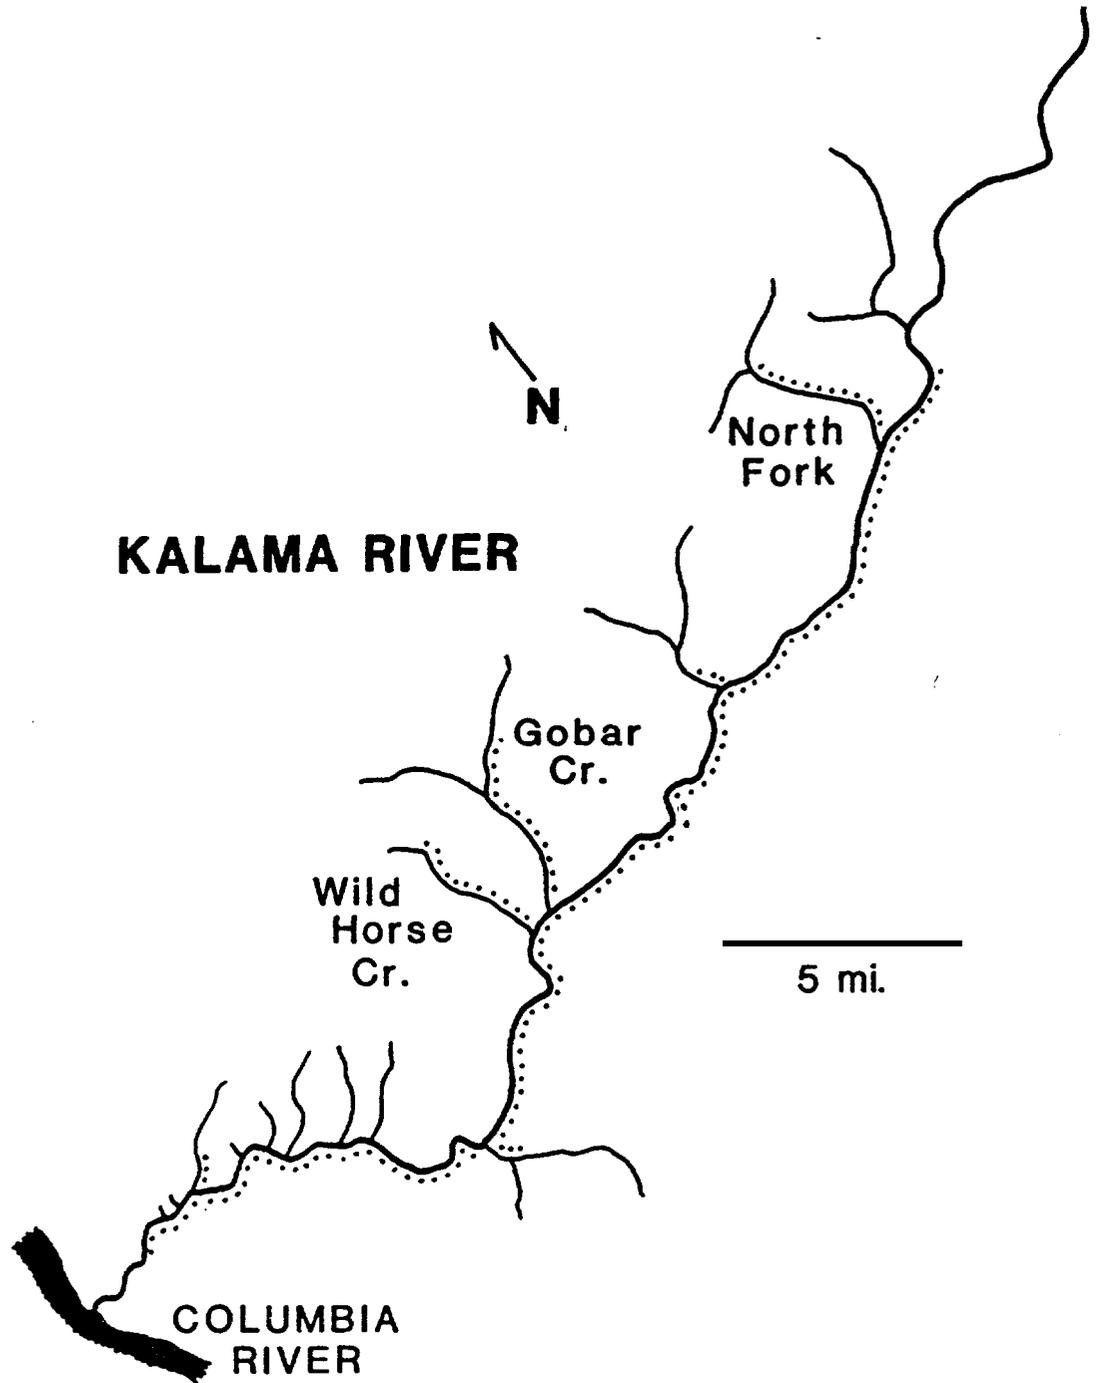

DISEASES

Disease history for smolts planted in the Kalama River is presented in Table 17.

^A**Sport** catch assumes WDW cut-offs between summer run and winter run fish although some months catch overlaps.

^B**Catch** within **subbasin** only.

^C**Escapement** numbers currently being updated which may change numbers stated above.

Escapement based on several factors; 1) adjusted rack returns of hatchery and wild fish counted at Kalama Falls,

2) exploitation rate of fish handled at Kalama Falls, 3) ratio of fish that jumped the falls, 4) data generated from tagging studies.

Sport catch based on angler returns of punchcards to Washington Department of Wildlife.

Escapement numbers include strays, particularly in 1980-1981 due to the eruption of Mount St. Helens.

^AThe Kalama River receives steelhead smolts from fish reared at Skamania Hatchery. Disease history for the Skamania Hatchery is located in the **subbasin** report for the Washougal River.

^BGobar pond is a rearing pond located on **Gobar** Creek, a tributary of the Kalama River.

^CBeaver Creek Hatchery is located on the Elochoman River.

Disease history only represents pathogens isolated at the hatchery and not necessarily a disease outbreak.

Source: WDW pathologist, Steve Roberts, 1991.

KALAMA RIVER SUBBASIN

Naturally Produced Winter Steelhead

GEOGRAPHIC LOCATION

The **Kalama Subbasin** is located in southwest Washington and although the headwaters are located in Skamania County, over 98 percent of the basin is in Cowlitz County. The Kalama originates on the southwest slope of Mount St. Helens and flows 44.5 miles west-southwest where it enters the Columbia River below Bonneville Dam at River Mile (RM) 73.1. The **subbasin** encompasses a drainage of approximately 205 square miles.

ORIGIN

The wild winter steelhead in the Kalama River is native, although interbreeding has occurred with introduced Chambers Creek, **Cowlitz** and Elochoman hatchery-stocks. In addition, steelhead which abandoned the Cowlitz system following the eruption of Mount St. Helens in 1980, strayed into the Kalama River and spawned with native Kalama steelhead.

It should be noted that Chilcote et al. (1980) and Leider et al. (1984) observed known summer steelhead spawning with winter steelhead showing that Kalama River winter and summer steelhead are not entirely reproductively separate.

DISTRIBUTION

Table 1 lists rearing and spawning habitat for Kalama River steelhead based on estimates from the Northwest Power Planning Council. Department of Wildlife estimates based on gradient, area and flow methodology is presented in Table 2. Winter and summer steelhead distribution is illustrated in the prior section's map of the Kalama River.

For steelhead to migrate into the upper Kalama River, fish must cross over a falls located at Kalama Falls Hatchery at RM 10. The falls has been **laddered** to allow fish passage, although tagging studies and visual observations indicate that fish jump the falls in greater numbers than use the fish ladder. A barrier which blocks all anadromous fish migration is a falls approximately 35 feet high at RM 36.8.

PRODUCTION

Production Facilities

There are two hatcheries in the subbasin, the Lower Kalama Salmon Hatchery located at RM 4.3 and Kalama Falls Salmon Hatchery located at RM 10. Both hatcheries produce chinook and **coho** salmon. Steelhead are acclimated for 1-2 months at **Gobar** Pond which is located approximately four miles up **Gobar** Creek, a major tributary of the Kalama River. **Gobar** Creek is located approximately 19.5 miles upstream from the mouth of the Kalama River. **Gobar** Pond consists of a 1.5 acre dirt bottom pond about 5 or 6 feet in depth with a **flow** of 2.5 CFS using **Gobar** Creek water. **Gobar** Pond was constructed as a short term rearing station which would acclimate steelhead prior to release, so returns and subsequent sport catch would be enhanced.

Production Summary

Limited data is available on wild smolt production. Number of steelhead smolts counted migrating out of the Kalama River from 1978 through 1984 ranged from 11,175 in 1982 to 46,659 in 1983 (Tables 6 and 7). Production constraints include tributaries which are short and have high gradients, habitat degradation, lack of quality spawning gravel, and stressful summer time high water temperatures.

ADULT LIFE HISTORY

Run Size and Escapement

Estimates of total run size (sport catch and escapement) from 1981 through 1989 ranged from 3,242 fish in 1988-89 to 6,201 fish in 1985-86 (Table 3). Escapement for wild steelhead from 1980 through 1989 ranged from 748 fish in 1982-83 to 2,928 in 1980-81 (Tables 3 and 4). Returns were exceedingly high in 1980-81 due to excessive straying of Cowlitz River steelhead caused by the eruption of Mount St. Helens in 1980. Estimates of hatchery-stock escapement listed in Table 5.

Time of migration

Adult time of entry for winter steelhead is generally from mid-November through June with peak returns occurring in February through April (**Leider** et al. 1991). Figure 1 illustrates the freshwater life history of winter steelhead in the Kalama **subbasin** (Kalama **Subbasin** Production Plan, 1990)

Harvest

Ocean catch of Kalama River winter steelhead is unknown. Kalama River winter steelhead harvested in the Columbia River has been estimated at 6.2 percent.

Sport harvest (hatchery and wild fish), based on permit-card harvest estimates, from 1981 through 1990 ranged from 1,811 in 1983-84 to 5,473 fish in 1980-81 although 1980-81 was an abnormally high return year due to the eruption of Mount St. Helens. From 1976 through 1986 harvest was estimated to contain 48.8 percent hatchery fish and 53.3 percent natural fish. Sport fishing is open year around below Kalama Falls with a two fish catch limit. Winter steelhead wild release regulations were imposed on the Kalama in 1990, limiting legal harvest to hatchery **fish** only. Table 2 lists yearly sport catch of Kalama River Winter steelhead from 1980 through 1990.

Spawning -period

Spawning, as measured in **Gobar** Creek, occurred from March through May. Average spawning time for hatchery and wild steelhead was March and April, respectively (**Leider** et al. 1991).

Spawning area

Winter steelhead spawn throughout most of the **mainstem** Kalama River and in various tributaries including **Gobar** and Wild Horse creeks. **Leider** et al. (1984) suggested that winter steelhead tended to spawn in the lower reaches of **Gobar** Creek (in contrast to summer steelhead).

Fecundity

No data is available for the Kalama River.

Age composition

Ages of wild winter steelhead were obtained from adults trapped at Kalama Falls Hatchery. Fish sampled from 1980 through 1990, an average of 3.0% were 1-ocean, 49.6% were **2-ocean**, 35.5% were **3-ocean**, and 9.7 % were repeat spawners (Tables 10 and 11).

Size

Mean lengths of wild adult steelhead sampled at Kalama Falls Hatchery were 65.7 cm for **2-ocean** fish, 81.9 for **3-ocean** fish 73.7 for repeat spawners (Table 13).

Sex ratio

Sex ratio for winter wild/hatchery steelhead for the five years 1979-1984 averaged 58.4% female for hatchery fish and 56.2% female for wild fish. Table 12 shows yearly female percentages for 1979-1984.

Survival rate

No data is available on wild winter steelhead.

JUVENILE LIFE HISTORY

Egg

No data is available on egg production or egg to smolt survival.

Emergence

Emergence occurs from April through early July (Kalama Subbasin Plan, 1990).

Juvenile rearing

Juvenile rearing lasts approximately two years prior to ocean emigration, although some juveniles emigrate after one or three years (Loch et al. 1985; Table 8).

Migration generally occurs from March through June with peak migration from mid-April to mid-May. Based on smolts captured from both the Kalama River and **Gobar** Creek sizes ranged from 137.1 mm to 167.8 mm (Table 9).

Hatchery releases

The Kalama River receives a yearly allotment of winter steelhead hatchery smolts. Hatchery pre-smolts are transferred to **Gobar** Pond in February. Until 1988 most smolts conditioned in **Gobar** pond were trucked to release sites on the lower Kalama River while some fish were released directly into **Gobar** Creek. In 1988 and 1989, all fish reared in **Gobar** Pond were released into the lower Kalama River. Since 1990, all fish reared in **Gobar** Pond have been released directly into **Gobar** Creek. The **Cowlitz**, and Beaver Creek Hatcheries have released smolts directly into the Kalama River. Steelhead smolts are released as yearlings. Table 14 outlines the history of winter steelhead plants from 1981 to 1991.

Straying

No data are available on Kalama River steelhead.

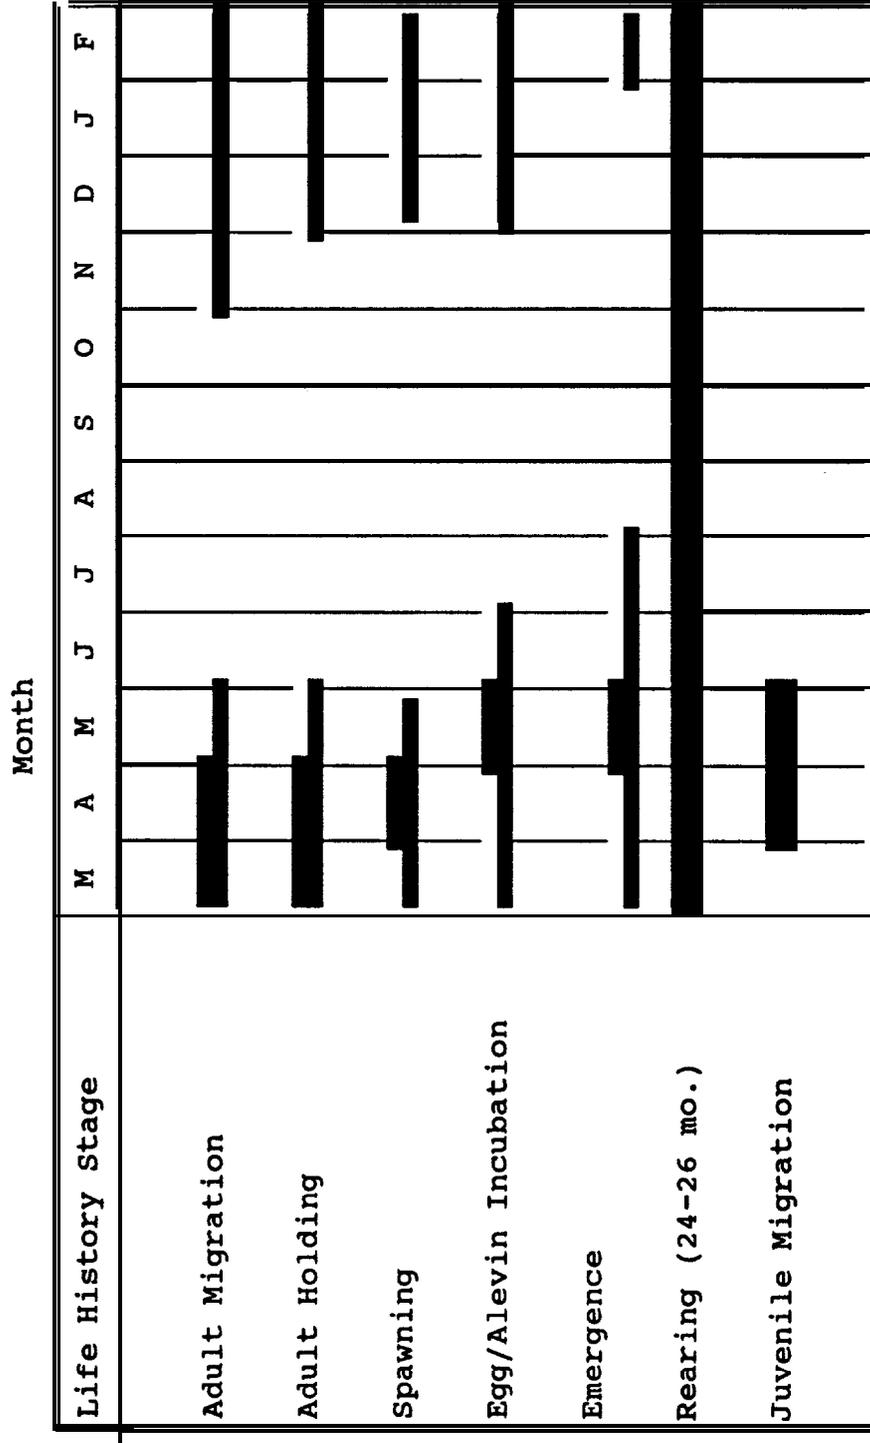

BIOCHEMICAL-GENETIC CHARACTERISTICS

Milner et al. (1980) did an electrophoretic profile of Kalama winter steelhead as part of overall study of Columbia River stocks and the feasibility of using biochemical genetic variation for estimating composition of mixed-stock fisheries. The study concluded sufficient genetic differentiation existed to do so. Since the mid-1970's The Washington Department of Wildlife's Kalama River Research Group has undertaken extensive studies examining reproductive success of hatchery versus wild winter steelhead. Detailed data exists showing genetic profiles, based on electrophoresis, of Kalama River winter steelhead.

DISEASES

Disease history for smolts planted in the Kalama River is presented in Table 15.

Figure 1 (TT). Freshwater life history of subbasin winter steelhead. The developmental stage timing represents basinwide averages; local conditions may cause some variability.

Based on the Kalama Subbasin Production Plan (1990).

^aThe Kalama River receives steelhead smolts from fish reared at Skamania Hatchery. Disease history for the Skamania Hatchery is located in the subbasin plan for the Washougal River.

^bGobar pond is a rearing pond located on Gobar Creek, a tributary of the Kalama River.

^cBeaver Creek Hatchery is located on the Elochoman River.

Disease history only represents pathogens isolated at the hatchery and not necessarily a disease outbreak.

LEWIS SUBBASIN

Spring Chinook

GEOGRAPHIC LOCATION

The Lewis River headwaters **decend** from the southern flanks of Mount Adams and Mount St. Helens. The **mainstem** of the river, also known as the North Fork Lewis River, flows southwesterly from its source in **Skamania** county through three impoundments, Merwin Lake at River Mile (RM) 19, Yale Lake RM 34, and Swift Creek Reservoir RM 48. Along the middle and lower sections, the river forms the boundary between Clark and **Cowlitz** counties. A major tributary, East Fork Lewis River, enters the **mainstem** at RM 3. From this point the Lewis River continues west, entering the Columbia River at RM 88. Lewis River Hatchery is located at RM 12. Speelyai Hatchery is located at Speelyai Bay on Merwin Reservoir.

ORIGIN

At one time, an indigenous stock of spring chinook existed in the Lewis River, but with the construction of Merwin Dam in 1931, the majority of the spawning reaches became inaccessible and the stock subsequently declined. Early attempts to save the stock through hatchery production failed. In the Lewis River, spring chinook eggs were collected for hatchery production in 1926 and 1927 and **from** 1931-1941 except for 1936. By 1950, only a remnant population existed in the river, spawning primarily in the waters immediately below Merwin Dam and Cedar Creek (Howell et al. 1985).

Lewis River spring chinook stock sources and hatchery production levels have changed frequently since the initial release of **Cowlitz** fingerlings in 1972. Since then, releases have been made from both the Speelyai and the Lewis River Hatcheries. Brood stock for the Lewis hatchery programs originated from a variety of sources including Cowlitz, Kalama, Carson, and even Klickitat stock. The stocks used now include Cowlitz and Kalama, along with onstation returns to the Lewis River (Howell et al. 1985). Local stock is collected by voluntary returns to Lewis River Hatchery or fish trapped at Merwin Dam. Only a few hundred spring chinook return annually to the Lewis hatchery due to poor trapping efficiency. Only occasional hatchery releases have been made into the East Fork Lewis River.

DISTRIBUTION

Nearly all of the spawning on the North Lewis River occurs in a four mile reach from Merwin Dam downstream to the Lewis River Hatchery. Few if any spring chinook return to the East Fork Lewis River.

PRODUCTION

Hatchery production is currently the dominant component in the Lewis River. According to the Merwin Dam mitigation agreement, Pacific Power and Light will be responsible for spring chinook production at the level of achieving annual run sizes of 12,800 adults. Both the Lewis and Speelyai Hatcheries continue to release spring chinook as part of their annual programs.

Tables that describe the amount of spring chinook spawning and **rearing** habitat in the Lewis River were not listed in the Presence/Absence database of Northwest Power Planning Council, 1991.

The North Fork Lewis River spring chinook natural spawn escapement from 1978-1984 brood years averaged 2,955 with a low return of 559 for the 1979 brood and a peak of 8,044 for the 1983 brood. North Fork Lewis River natural spawn escapements by age and brood year are presented in Table 1.

Lewis River hatcheries spring chinook returns from 1978-1984 brood years averaged 425 with a low return of 89 for the 1979 brood and a peak of 783 for the 1984 brood. Lewis River hatcheries returns by age and brood year are presented in Table 2.

The North Fork Lewis **tributary** sport catches from 1978-1984 brood years averaged 5,504 with a low catch of 1,946 for the **1979** brood and a peak of 9,232 for the 1982 brood (based on punch card and actual sampling data). North Fork Lewis River tributary sport catches by age and brood year are presented in Table 3.

The North Fork Lewis spring chinook total returns from 1978-1984 brood years averaged 8,883 with a low return of 2,594 for the 1979 brood and a peak of 17,417 for the 1983 brood. North Fork Lewis spring chinook total returns by age and brood year are presented in Table 4.

ADULT LIFE HISTORY

Run size, catch and escapement

Ocean commercial and recreational fisheries from Alaska to Washington, in addition to Columbia River gill net and sport fisheries, all harvest a portion of the Lewis River origin spring chinook. Although the spring chinook has a low contribution rate in terms of ocean harvest, tributary sport catch harvested an average of 69 percent of the total spring chinook return to the Lewis River between 1977-1987 (**WDF**, 1990). Columbia River sport and commercial fisheries have not been curtailed by North Fork Lewis River escapement concerns.

Strays from other lower river hatcheries are unusual. Table 5 lists the coded wire tags recovered within the Lewis **subbasin** which originated outside the Lewis subbasin. Lewis River hatcheries spring chinook releases are generally untagged.

Time of Migration

Upstream migration begins in early April and May.

Spawning Period

Spawning extends from late August to early October with peak activity in September.

Spawning Areas

Nearly all of the spawning on the North Fork Lewis River occurs from Merwin Dam downstream to the Lewis River Hatchery. Few if any spring chinook return to the East Fork Lewis River.

Age Composition

Age ranges from two-year-old mini jacks to six-year-old adults. The adult run is primarily composed of four-year-old and five-year-old fish with a minor number of six-year-olds. Table 6 lists the age composition percentages by brood year and **freshwater.ocean** rearing for spring chinook returning to the North Fork Lewis River spawning grounds. Table 7 lists the age composition

percentages by brood year and **freshwater.ocean** rearing for spring chinook returning to the Lewis River hatcheries. Table 8 lists the age composition percentages by brood year for spring chinook caught in the North Fork Lewis sport fishery.

Sex Ratio

Female chinook comprised 47-63 percent of the spring chinook returning to the Lewis River and Speelyai Hatcheries between 1979-1988 return years (WDF, 1990). The percentage of females by age class (**freshwater.ocean**) for recent years of natural escapements, and hatchery returns are listed in Tables 9 and 10.

The mean fork length by brood year, sex, and **freshwater.ocean** rearing ages of North Fork Lewis natural spawners for 1982-1987 brood years are available in Tables 11 and 12. The mean fork length by brood year, sex, and **freshwater.ocean** rearing ages for Lewis River hatcheries returns are available in Tables 13 and 14.

Fecundity

Fecundity at the Lewis River and Speelyai Hatcheries between 1979-1988 return years averaged 4,083 and ranged from a low of 3,547 in 1980 to a high of 4,510 in 1982. Lewis River natural spawn and hatchery fecundity data by age and brood year is unavailable.

JUVENILE LIFE HISTORY

Time of Emergence

Incubation occurs from September through December, followed by emergence from December into January (WDF, 1990).

Time, age and size at migration

Under natural conditions, outmigration of juveniles generally takes place as yearlings, leaving the river during May and June. Since spring chinook in the North Fork Lewis **River are** of hatchery origin, outmigration is dependent on release. The majority of releases at the two hatcheries been of fingerlings and yearlings. Fish are generally released on station into the North Fork or **mainstem** Lewis although some off-station releases have been made into the East Fork Lewis River. Releases have also been made into Merwin Lake above the dam. Hatchery release information for the Lewis **subbasin** by brood year is presented in Table 15.

Length data of natural spring chinook smolts that migrate from the Lewis River **subbasin** is unavailable. The number of natural juvenile spring chinook that migrate from the Lewis **subbasin** is also unavailable.

Survival Rate

Smolt-to-adult survival was about 2.0 percent for two 1973 brood coded wire tagged groups of Carson stock spring chinook reared at Speelyai Hatchery and released into the North Fork Lewis River (TAC, 1984).

Egg-to-smolt survival rate at Lewis River and Speelyai Hatcheries between 1981-1987 brood years averaged 76.1 percent and ranged from a low of 68.8 in 1986 to a high of 84.1 in 1984 (WDF, 1990). Lewis River natural spawn survival rate is unavailable.

Studies conducted in the early 1970's, based on coded-wire tags, indicated higher levels of returns for fingerlings as opposed to yearling releases. This information, however, is based only on a two year program (McIsaac and Fiscus 1979).

BIOCHEMICAL-GENETIC CHARACTERISTICS

Data is unavailable.

DISEASE

Bacteria and parasitic diseases found in the Lewis River hatcheries are listed in Table 16 (WDF Salmon Culture, Olympia).

Table 16 (TD-1). Parasites and diseases of spring chinook at the North Fork Lewis River hatcheries.

Disease type	Hatchery	Specific Pathogen
Virus	Lewis River	IHN - Infectious Hematopoietic Necrosis
Bacteria	Lewis River	<i>Aeromonas salmonicida</i> (Furunculosis)
Bacteria	Lewis River	<i>Yersinia ruckeri</i> (Enteric Redmouth)
Bacteria	Lewis River	<i>Renibacterium salmoninarium</i> (Bacterial Kidney Disease)
Parasite	Lewis River	Various Ectoparasites, Endoparasites and Myxosporidians
Parasite	Lewis River	<i>Saprolegnia parasitica</i> (Fungus)
Virus	Speelyai	IHN - Infectious Hematopietic Necrosis
Bacteria	Speelyai	<i>Aeromonas salmonicida</i> (Furunculosis)
Bacteria	Speelyai	<i>Yersinia ruckeri</i> (Enteric Redmouth)
Bacteria	Speelyai	<i>Renibacterium salmoninarium</i> (Bacterial Kidney Disease)
Parasite	Speelyai	<i>Saprolegnia parasitica</i> (Fungus)

Disease history only represents pathogens isolated at the hatchery and not necessarily a disease outbreak.

LEWIS SUBBASIN

Fall Chinook

GEOGRAPHIC LOCATION

The Lewis River headwaters descend from the southern flanks of Mount Adams and Mount St. Helens. The **mainstem** of the river, also known as the North Fork Lewis River, flows southwesterly from its source in Skamania County through three impoundments, Merwin Lake at River Mile (RM) 19, Yale Lake RM 34, and Swift Creek Reservoir RM 48. Along the middle and lower sections, the river forms the boundary between Clark and **Cowlitz** counties. A major tributary, East Fork Lewis River, enters the **mainstem** at RM 3. From this point the Lewis River continues west, entering the Columbia River at RM 88. Lewis River Hatchery is located at RM 12. Speelyai Hatchery is located at Speelyai Bay on Merwin Reservoir.

ORIGIN

A native population of fall chinook was in existence on the North Fork Lewis River prior to construction of the Lewis River Hatchery in 1930. The stock of fall chinook in the Lewis system has maintained a significant population with negligible hatchery influences, unlike any other lower Columbia River stock (**McIsaac** 1979).

The North Fork Lewis River wild fall chinook represent about 80 to 85 percent of the wild fall chinook returning to the Lower Columbia River (Norman, 1987).

DISTRIBUTION

Nearly all of the spawning on the North Fork Lewis River occurs from Merwin Dam RM 16 downstream to the Lewis River Hatchery. East Fork Lewis River fall chinook spawning ground surveys are conducted annually within the 4.2 mile stretch from the area of the Lewisville Park to Daybreak Park.

PRODUCTION

Both the North and East Fork Lewis Rivers current fall chinook production is entirely natural.

North Fork Lewis River hatchery production of fall chinook have been inconsistent in terms of numbers and types of releases. Some release groups were for experimental rather than production purposes. Since 1971, progeny releases from adults collected at Merwin Dam did not exceed **550,000** fingerlings and typically ranged from 50,000 to 150,000 fish. Most of those releases were offspring of an early spawning segment of the run (Howell et al. 1985). No fall chinook have been planted since 1985.

Tables 1 and 2 describe the amount and quality of spawning and rearing habitat available in the North Fork Lewis River. This data was derived from the Presence/Absence database of the Northwest Power Planning Council, 199 1.

The North Fork Lewis River fall chinook natural spawn escapement from 1978-1984 brood years averaged 13,663 with a low return of 7,345 for the 1980 brood and a peak of 26,486 for the 1984 brood. The East Fork Lewis River fall chinook natural spawn escapement from 1978-1984 brood years averaged 454 with a low return of 356 for the 1982 brood and a peak of 787 for the 1984 brood. North and East Forks Lewis natural spawn escapements by age and brood year are presented in Tables 3 and 4.

North Fork Lewis River hatcheries return from 1979-1984 brood years averaged 368 with a low of 112 for the 1984 brood and a peak of **571** for the 1980 brood. Hatchery returns by age are presented in Table 5.

North Fork Lewis River tributary sport catch estimates between 1977-1987 return years averaged 1,079 fall chinook, ranging from a low of 968 for the 1979 **brood** and a peak of 3,306 for the 1981 brood (based on punchcard data). Jacks comprise approximately 50 percent of the harvest (WDF, 1990). However, specific age and brood year analysis for the North and East Fork **Lewis** Rivers sport catches are unavailable.

ADULT LIFE **HISTORY**

Run size, catch and escapement

Ocean commercial and recreational fisheries from Alaska to Washington harvest Lewis River fall chinook. Based on coded wire recoveries of 1977 brood North Fork Lewis River wild stock, most of the overall ocean harvest occurs in the Alaska and British Columbia troll fisheries (Howell, 1985). In addition, Columbia River gill net and sport fisheries all harvest a portion of the Lewis River origin fall chinook. The tributary sport fishery in the North Fork Lewis River harvests a larger percentage of the North Fork Lewis River run compared to tributary fisheries for other major Columbia River fall chinook stocks. Sport catches within the **subbasin** normally comprise 15 percent of the total returns (WDF, 1990). The Lower River Wild (**LRW**) stock has never been a constraining stock of Columbia **River** sport and commercial fisheries.

The North Fork Lewis River has a large enough escapement to sustain the naturally spawning population. A maximum sustained yield spawning escapement estimate of 5,700 adult spawners has been recommended by Don **McIsaac** (1990).

Strays from other lower river hatcheries are not unusual. Table 6 lists North Fork Lewis River hatchery and wild origin fall chinook stray coded wire tag recoveries **beginning with** the 1978 brood through to the 1988 brood. The coded wire tags recovered within the North and East Fork Lewis Rivers which originated outside the Lewis **subbasin** are listed in Tables 7 and 8 respectively.

Time of Migration

Upstream migration begins from August to September and peaks in September and October, depending partly on early fall rains. However, North Fork Lewis River wild stock fall chinook have been caught in the North Fork Lewis River sport fishery as early as July (based on coded wire tag recoveries) and observed as late as April 19, 1985, when live fall chinook and fresh redds were found in the North Fork Lewis River (Howell, 1985).

Spawning Period

During spawning surveys on the North Fork Lewis River conducted between 1964 and 1982, peak fish count averaged about November 13 (Norman, 1984). In the East Fork Lewis River, two distinct spawning segments are evident. The early segment spawns in October while the late segment spawns November through January.

Spawning Areas

Nearly all of the spawning on the North Fork Lewis River occurs from Merwin Dam downstream to the Lewis River Hatchery. Some fall chinook spawning has also been observed in Cedar Creek. East Fork Lewis River spawning ground surveys are conducted between Lewisville and Daybreak Parks.

Age Composition

Age ranges from two-year-old jacks to six-year-old adults with four-year-olds the dominant age class. Total age composition data is summarized in Tables 3 through 5. Tables 9 and 10 respectively list the age composition percentages by brood year and **freshwater.ocean** rearing for fall chinook returning to the North and East Fork Lewis Rivers spawning grounds. Age composition percentages by brood year and freshwater-ocean rearing for fall chinook returning to the Lewis River hatcheries are unavailable.

Sex Ratio

Female fall chinook comprised 43-49 percent of the natural spawners in the North Fork Lewis River between 1981-1984 brood years. Female fall chinook comprised 30-47 percent of the natural spawners in the East Fork Lewis River between 1981-1984 brood years. The percent females by brood year and freshwater-ocean rearing ages for North and East Fork Lewis Rivers natural spawners are presented in Tables 11 and 12 respectively.

Based on hatchery returns, female fall chinook comprised 45-71 percent of the fall chinook between 1979-1985 return years (**WDF**, 1990). A percentage of females by brood year and age class is unavailable.

The mean fork length by brood year, sex, and freshwater-ocean rearing ages of North and East Fork Lewis Rivers natural spawners for the 1978-1984 brood years are available in Tables 13 through 16.

Fecundity

Fecundity at the Lewis River Hatchery between 1979-1985 return years averaged 4,429 and ranged from a low of 3,269 in 1984 to a high of 4,956 in 1981 (**WDF**, 1990). Lewis River natural spawn and hatchery fecundity data by age and brood year are unavailable.

JUVENILE LIFE HISTORY

Time of Emergence

Since 1976, juvenile fall chinook have been seined from the North Fork Lewis River as part of an investigation of wild stock rearing and adult production. A primary task of this study has been the collection and coded wire tagging of naturally produced fingerlings and fry. Recently emerged fry (30-40 mm.) have been observed as early as March 23 (**McIsaac**, 1980) and as late as August 22 (**WDF**, 1990). An early March timing for emergence coincides with the 1,800 Temperature Units (TU's) required for chinook fry emergence if the eggs were deposited in early November (**McIsaac**, 1980). Peak of emergence occurs during April (**WDF**, 1990). No fall chinook time of emergence data is available for the East Fork Lewis River.

Time, age and size at migration

The number of wild juvenile fall chinook that migrated from the North Fork Lewis River between 1977-1987 (excluding 1980 and 1981) has averaged **2,786,667** and ranged from a low of **1,540,000** for the 1986 brood and a peak of **4,650,000** for the 1983 brood (estimates are based on simple Peterson recapture method using coded wire tags recovered from adult returns). Table 17 lists the number of natural fall chinook that migrated from the North Fork Lewis 1977-1979 and 1982-1987. Hatchery release information for the Lewis River **subbasin** by brood year is presented in Table 18.

Coded wire tagged North Fork Lewis River fall chinook were recovered in the Columbia estuary primarily in early August, illustrating the extended freshwater rearing of this population. This

estuary recovery information combined with the August seine catches in the North Lewis, demonstrates the significance of rearing in the natal stream. Most juveniles migrate from the North Fork Lewis River in mid to late summer at approximately 90 mm in length. This data is based on North Fork Lewis River wild juvenile fall chinook seined, marked, coded wire tagged, and released immediately into the North Fork Lewis River and subsequently **recaptured** at Jones Beach (Columbia River Km 75) by beach seine gear operated by the **National Marine** Fisheries Service during July through September 1978-1980 (**Dawley** et al. 1982). The mean fork lengths of coded wire tagged wild fall chinook recaptured from the North Fork Lewis River from 1983 to 1989 ranged from 69 to 86 mm during late June-August post tagging seining evaluations. Average lengths and ranges of North Fork Lewis River wild fall chinook **smolts** are presented in Tables 19 and 20. Based on scale analysis, ocean entry of the juveniles occurs primarily in the fall but a few remain in freshwater until the following spring and enter the ocean as yearlings.

No hatchery fall chinook releases have been made in the North Fork Lewis River since 1985.

Survival Rate

North Fork Lewis River fall chinook smolt to adult survival rates measured in terms of all catch and escapement was 1.7 percent based on the 14 tag groups originating from the 1977 through 1979 brood years (**WDF**, 1990).

Hatchery fall chinook egg to smolt survival rates from 1979-1985 return years averaged 71 percent with a low of 57 percent in 1982 and a peak of 90 percent in 1985 (**WDF**, 1990).

No fall chinook survival information is available for the East Fork Lewis River.

BIOCHEMICAL-GENETIC CHARACTERISTICS

Shreck, et al. (1986) found a statistically significant difference in gene frequencies for one enzyme system between Lewis River Hatchery returns and the naturally spawning fish, which indicated a genetic difference between the two groups. Based on coded wire tag recoveries, strays from Lower River Hatchery production areas are known to enter the Merwin Dam fish trap. This straying could explain the electrophoretic difference.

DISEASE

Information on bacteria and parasitic diseases **occurring** in Lewis River fall chinook production is unavailable.

Table 1 (HB-1). Estimated amount of rearing and spawning habitat, by quality, of the North Fork Lewis River fall chinook production area.

Distance/Area	Excellent	Good	Fair ^a	Poor ^a	Unknown	Total	Confidence
Miles (%)	37	62	01	00		39.1

Table 6. (cont.) Emigration of coded wire tagged fall chinook from the (North Fork) Lewis subbasin.

Based on the following tag codes: 63-19-50, 63-19-10, 63-19-20, 63-19-50, HI-02-05, 63-18-58, 63-20-02, 63-21-23, 63-21-60, 63-18-59, 63-18-13, 63-20-21, 63-27-38, 63-31-27, 63-34-12, 63-38-21, 63-50-62, 63-27-37, 63-34-11, 63-38-22, 63-41-51, 63-41-53, **63-50-61**, 63-50-62, 63-21-57, 63-23-29, 63-34-09, 63-34-10, and 63-20-21.

Does not include Lewis wild reared at Speelyai Hatchery and recovered at Speelyai Hatchery, or Speelyai Hatchery fish recovered at Lewis River spawning grounds.

Does not include 1976, 1978, and 1979 brood wild fall chinook reared at Lewis and Speelyai Hatcheries and released into the North Fork Lewis River.

Beginning with the 1978 brood.

Table 7 (AI-1). Immigration of coded wire tagged fall chinook into the (North Fork) Lewis River subbasin.

Jones Reach (Columbia River Km 75), 1978	145	94	?	“Factors Affecting the Abundance of 1977-79 brood wild fall chinook salmon in the North Fork Lewis River, Washington” by Don McIssac , University of Washington dissertation, 1990.
Jones Reach (Columbia River Km 75), 1979	797	84	?	Same as above.
Jones Reach (Columbia River Km 75), 1980	568	93	?	Same as above.

NMFS intensively sampled outmigrating juvenile salmonids at the head of the Columbia River estuary (Jones Reach, River Km 75) from 1978 through 1980. A sample of the daily catch of chinook salmon with missing adipose fins was sacrificed and measured by NMFS to obtain CWT and length information. Actual catches of marked and tagged chinook salmon were adjusted by the original researchers to represent estimates from a standard effort of 10 sets per day for seven days per week. Numbers of fish examined are the estimated number of North Fork Lewis River wild juvenile fall chinook seined, marked, tagged and released immediately into the North Fork Lewis and subsequently recaptured July-September at Jones **Beach** (Columbia River) with beach seine gear operated by the NMFS.

LEWIS SUBBASIN

Coho Salmon

GEOGRAPHIC LOCATION

The Lewis River headwaters descend from the southern flanks of Mount Adams and Mount St. Helens. The **mainstem** of the river, also known as the North Fork Lewis River, flows southwesterly from its source in Skamania County through three impoundments, Merwin Lake at River Mile (RM) 19, Yale Lake RM 34, and Swift Creek Reservoir RM 48. Along the middle and lower **sections**, the river forms the boundary between Clark and Cowlitz counties. A major tributary, East Fork Lewis River, enters the **mainstem** at RM 3. From this point the Lewis River continues west, entering the Columbia River at RM 88. Lewis River Hatchery is located at RM 12. Speelyai Hatchery is located at Speelyai Bay on Merwin Reservoir.

ORIGIN

The Lewis River historically had excellent runs of **coho** salmon. Before the construction of Merwin, **coho** spawned in the headwater tributaries of Pine Creek RM 59 and Muddy River RM 60, including Clearwater and Clear Creeks (WDF, 1990). Most existing early **coho** (Type-S). hatchery programs are considered to be linked to native Toutle River stock **coho**. Washington stations either received Toutle stock eggs or utilized local native early run **coho**. Late stock **coho** (Type-N) are informally considered synonymous with Cowlitz River stock **coho**. Late stock hatchery programs were developed utilizing Cowlitz River stock, their derivatives, or native late runs. Late **coho** used in most of the current programs are presumably a blend of all of these, although egg transfers from Cowlitz Hatchery occur most frequently (Howell et al. 1985). The Lewis and Speelyai hatcheries have both stocks of **coho**.

DISTRIBUTION

Natural spawning occurs in most areas accessible to **coho**. Historically spawning on the Lewis occurred throughout the watershed. The most extensively utilized stream of the North Fork Lewis River is Cedar Creek. Coho travel upstream for 15 miles into North and South Fork Chelatchie Creeks. On low water flow years **coho** spawn intensively in the North Fork Lewis River upstream from the Lewis River Hatchery to Merwin Dam.

On the East Fork Lewis River **coho** spawning occurs below Lucia Falls (RM 21), particularly in side channel areas. Lockwood, Mason, and Rock Creeks are extensively used by spawning **coho** (WDF, 1973). Some spawning does occur above Lucia Falls but high river flow is needed for fish passage.

PRODUCTION

Despite the blockage by Merwin Dam, **coho** continue to return in good numbers due to the hatchery program started in 1930. In 1951, the Washington Department of Fisheries estimated **coho** escapement in the North Fork Lewis to be about 10,000 and the East Fork Lewis at about 5,000 (WDF, 1990). After Merwin was built, but before Yale was constructed, **coho** were trapped immediately below Merwin and released into the reservoir to utilize upstream habitat (WDF, 1990).

In Washington and Oregon adult production of early and late **coho** from natural spawners is unknown except for a few instances. A factor of 10 - 15 percent might be considered reasonable for

the percent of the total Columbia River **coho** production originating from naturally spawning fish (Howell et al. 1985). Escapement estimates are based solely of returns to the hatchery (WDF, 1990).

Tables 1 and 2 describe the amount of spawning and rearing habitat, by quality, available in the Lewis River. This data was derived from the Presence/Absence database of the Northwest Power Planning council, 1991.

The number of Lewis River **coho** natural spawn escapement is unavailable. Lewis and Speelyai early **coho** returns during the 1978 - 1987 brood years averaged 8,803 fish and ranged from a low of 1,123 for the 1982 brood to a high of 16,241 for the 1979 brood. Lewis and Speelyai late **coho** returns during the 1980 - 1987 brood years averaged 30,451 fish and ranged from a low of 10,349 for the 1984 brood to a high of 62,208 for the 1983 brood. Lewis and Speelyai early and late **coho** returns by brood year are presented in Tables 3 and 4, respectively.

Lewis River tributary sport catch estimates between 1979 - 1988 return years averaged 2,275 adult **coho**, ranging from a low of 704 in 1981 to a high of 5,525 in 1980 based on punch cards and limited sampling data. Specific age and brood year analysis for Lewis River sport catch is unavailable.

ADULT LIFE HISTORY

Run size, catch and escapement

Ocean commercial and recreational fisheries off the Oregon coast are the primary harvesters of early **coho**. The Oregon troll fishery accounts for the highest percentage of the overall catch. Most of the freshwater recreational harvest occurs in the Washington tributaries (Howell et al. 1985).

Based on coded-wire tagged releases of 1976 - 1978 brood late **coho**, most of the harvest occurs in the Washington and Oregon ocean fisheries. Late **coho** have a more northerly migration pattern than early **coho** (WDF, 1990). This is reflected in the catch distribution where the Washington coastal catch comprised 40 percent of the total harvest compared to 20 percent for early **coho** during 1979 - 1981. Late **coho** also contribute significantly to the lower Columbia River commercial gill net fishery (Howell et al. 1985).

Strays from other lower river hatcheries are not unusual. Table 5 lists Lewis and Speelyai hatchery origin **coho** stray coded-wire tag recoveries beginning with the 1978 brood through to the 1988 brood. Coded-wire tags which originated outside the Lewis **subbasin** but were recovered within the Lewis **subbasin** are listed in Table 6.

Harvest rates have averaged 79 percent and 85 percent for Type-S and N stocks, respectively, between 1983 and 1987. Harvest of Type-S **coho** is occasionally constrained by one or more of the fall chinook stocks. Harvest of Type-N **coho** is generally not constrained by weak stocks, with hatchery escapement being the only management constraint (WDF, 1990).

Time of Migration

Early **coho** enter the Columbia River by mid-August and begin returning to the lower Columbia hatcheries in early September. In the **mainstem** Columbia River early **coho** are predominant from August to mid-September. Stock composition shifts to late **coho** in late September and October. Typically, the late **coho** run begins entering freshwater in mid to late September with mid-October

considered the main migratory period in the **mainstem** Columbia River (Howell et al. 1985).

Spawning Period

For Type-S **coho**, both hatchery and natural spawning occurs around late October, while for Type-N **coho** spawning will extend from late November through March, with the bulk being in December and early January (Howell et al. 1985)

Spawning Areas

Natural spawning occurs in most areas accessible to **coho** (Howell et al. 1985).

Age composition

Coho return as two-year-old jacks and three-year-old adults. Total early and late **coho** hatchery returns to the Lewis River are listed in Tables 3 and 4. Age composition percentages by brood year for early and late **coho** returning to the Lewis River hatcheries are listed in Tables 7 and 8, respectively. Age composition percentages by brood year for Lewis **subbasin** natural spawners are unavailable.

Sex Ratio

The number of Lewis River Hatchery adults for the 1979 - 1988 return year averaged 4,889 with a low return of 1,016 in 1985 and a high of 12,709 in 1982 (**WDF, 1990**). The percent of Lewis River Hatchery adult females for the return years 1979 -1988 averaged 0.39 percent with a low of 0.24 percent in 1987 and a high of 0.52 percent in 1979 (**WDF, 1990**). Specific percent females by brood year and age class (freshwaterocean) for **coho** naturally spawning is unavailable.

Fecundity

Fecundity at the Lewis and Speelyai hatcheries for the 1980 -1988 return years averaged 2,506 with a low of 2,042 in 1983 and a peak of 3,044 in 1988 (**WDF, 1990**).

Lewis River natural and hatchery fecundity data by age class and brood year are unavailable.

JUVENILE LIFE HISTORY

Time of Emergence

In the Lewis River, at 50 degrees Fahrenheit, fertilization to eyed-egg stage takes about 3.5 weeks, eyed-egg to hatching takes about 2.5 weeks, and hatching to emergence about 8 weeks (Howell et al. 1985). The juvenile life history for Lewis **subbasin coho** is similar to that of other stocks in the region with a spring emergence (**WDF, 1990**).

Time, age and size at migration

Hatchery release information for the Lewis **subbasin** by brood year is presented in Table 9. Because of pond capacity constraints, fingerlings usually constitute the majority of the production.

Survival Rate

A generalized recent year smolt to adult survival rate for **coho** was estimated to be 2.5 percent (**TAC** 1983, Howell et al. 1985).

BIOCHEMICAL-GENETIC CHARACTERISTICS

Data has not been compiled.

DISEASE

Bacteria and parasitic diseases found in the Lewis and Speelyai hatcheries are listed in Table 10 (**WDF Salmon** Culture, Olympia).

Table 1 (HB-1). Estimated amount of rearing and spawning habitat by quality of the Lewis River **coho** production area.

Distance/Area	Excellent	Good	Fair ^a	Poor ^a	Unknown	Total	Confidence
Miles (%)	00	77	23	00		64.1

1986	464	13,357	13,821	13,357
1987	451	4,733	5,184	4,733
1988	1,050			

Includes early **coho** returns to Lewis and **Speelyai** Hatcheries.

Age composition based on hatchery personnel designation of adults and jacks. Adults were assumed to 2.1 and jacks 2.0.

Table 4 (RH-2). Total hatchery **returns** of late **coho** to the Lewis River by brood year.

Total Age

Brood Year	2	3	Total	Adult Total
1978				
1979		10,803		
1980	9,019	13,410	22,429	13,410
1981	5,878	9,712	15,590	9,712
1982	1,983	9,236	11,219	9,236
1983	14,207	48,001	62,208	48,001
1984	1,313	9,036	10,349	9,036
1985	17,053	27,765	44,818	27,765
1986	13,634	34,998	48,632	34,998
1987	7,076	21,286	28,362	21,286
1988	6,613			

Includes late **coho** returns to Lewis and Speelyai hatcheries.
 Age composition based on hatchery **personnel** designation of adults and jacks.
 Adults were assumed to be 2.1 and jacks 2.0.

Table 5 (AE). Emigration of coded wire tagged **coho** from the North Fork Lewis subbasin.

Beginning with the 1978 brood,

Table 7 (AC-1). Age composition percentage (freshwaterocean) by brood year for early **coho** returning to the Lewis and Speelyai hatcheries.

Brood Year	N	2.0	2.1
1978		7.62%	92.38%
1979		21.75%	78.25%
1980		19.06%	80.94%
1981		56.43%	43.57%
1982		9.53%	90.47%
1983		18.24%	81.76%
1984		0.70%	99.30%
1985		58.19%	41.81%
1986		3.36%	96.64%
1987		8.70%	91.30%
1988			

Age composition based on hatchery personnel designation of adults and jacks.
 Adults assumed to be 2.1 and jacks 2.0.
 N (number of scales samples) not applicable.

Table 8 (AC-2). Age composition percentage (freshwaterocean) by brood year for late **coho** returning to the Lewis and Speelyai hatcheries.

Brood Year	N	2.0	2.1
1980		40.21%	59.79%
1981		37.70%	62.30%
1982		17.68%	82.32%
1983		22.84%	77.16%
1984		12.69%	87.31%
1985		38.05%	61.95%
1986		28.04%	71.96%
1987		24.95%	75.05%
1988			

Age composition based on hatchery personnel designation of adults and jacks.
 Adults assumed to be 2.1 and jacks 2.0.
 N (number of scales samples) not applicable.

Table 9 (TR). Hatchery releases of COHO salmon into the LEWIS RIVER subbasin sorted by brood year, hatchery and life stage.

LEWIS RIVER SUBBASIN

Naturally Produced Summer Steelhead

GEOGRAPHIC LOCATION

The Lewis drainage begins on the southern slopes of Mount St. Helens and Mount Adams. The **mainstem** of the river is known as the North Fork Lewis River which drains a watershed of 828 square miles. From its source, the North Fork flows southwest through three separate lakes, Swift Creek, Yale Lake and Merwin Reservoir before a major tributary, East Fork Lewis River, draining a watershed of 212 square miles joins the **mainstem** at river mile (RM) 3.5. From this point the Lewis River continues west, entering the Columbia River at RM 88.

ORIGIN

The wild summer steelhead stock in the Lewis River is native, although interbreeding with introduced Skamania hatchery stock has likely occurred. In addition, steelhead which abandoned the Cowlitz system following the eruption of Mount St. Helens in 1980, probably strayed into the Lewis River and spawned with native Lewis stock.

DISTRIBUTION

Table 1 lists rearing and spawning habitat, by quality, for Lewis River steelhead based on estimates from the Northwest Power Planning Council.

Current steelhead population distribution on the North Fork occurs from approximately RM 7 to RM 20 (Lewis River Production Plan, 1990). There are three dams (Swift, Yale, Merwin) which block passage of anadromous fish into the upper areas of the North Fork Lewis (Figure 1). A dam located on Cedar Creek, a tributary to the North Fork, was removed in 1946 and in combination with stream improvements spawning now occurs throughout most of Cedar Creek.

The East Fork Lewis River allows steelhead access and spawning throughout most of the river (Figure 2). The lower portion of the river is becoming increasingly impacted by urbanization while the upper portion remains relatively unchanged. Few steelhead were reported to have ascended sunset falls prior to 1982 when the falls were "notched." This lowered the falls from 13.5 ft to 8 ft and made the upper reaches more accessible. Now spawning takes place in the **mainstem** as well as Rock Creek and other tributaries. Summer run fish do not pass over the falls as readily as winter run fish (Howell et al.), and numerous small falls provide barriers to migrating adults during periods of low flow.

PRODUCTION

Production Facilities

There are two hatcheries in the subbasin, Lewis River Hatchery and Speelyai Hatchery. Lewis River Hatchery is located on the North Fork four miles below Merwin Dam. The hatchery is a major producer of **coho** salmon and also operates a spring chinook program. Speelyai Hatchery is located on Speelyai Creek, above Merwin Dam, also on the North Fork. The hatchery rears both **coho** and spring chinook salmon. An additional rearing facility (Ariel Hatchery) to be used for steelhead, rainbow and cutthroat trout production is planned, with construction targeted at the base of Merwin Dam. A net pen rearing system has been in operation since 1979 in Merwin Reservoir rearing a mean of 60,000 summer steelhead smolts for release annually on winter plants into the North Fork Lewis River.

Production Summary

No data are available on wild smolt production. Natural production continues in both the North and East Fork Lewis but estimates on smolt production do not exist. The lower section of the North Fork Lewis from Merwin Dam downstream is the only section available for fish production. Merwin Dam, a 240 foot high dam, blocks upstream passage and converts the middle sections of river into three large impoundments. The East Fork provides rearing habitat throughout most of the river. Although access to the upper reaches of the East Fork is difficult due to its steep gradient with numerous drops and waterfalls, excellent steelhead habitat can be found there.

ADULT LIFE HISTORY

Run Size and Escapement

Estimates of total run size and escapement is lacking with the exception of 1984 when wild summer steelhead entering the East Fork were estimated at 600 while wild steelhead entering the North Fork was estimated at less than 50 fish. Run size estimates for past years show steelhead returns between 1925 and 1933 estimated at 4,000 fish, while run size between 1963 and 1967 averaged 6,150 fish. In 1985 (Lucas B.) determined the wild portion of summer steelhead at Lucia Falls averaged 27 percent for fish creel between 1974 and 1983.

Time of migration

Adult time of entry for summer steelhead is generally from April through October with peak returns occurring in July (Lewis River Subbasin Plan, 1990). The freshwater life history of summer steelhead in the Lewis River is depicted in Figure 3.

Harvest

Ocean harvest of Lewis River wild summer steelhead is unknown.

The amount of Columbia River harvest is unknown, however, large numbers of steelhead are harvested by the sport fishery on the Columbia River as well as treaty Indian fisheries above Bonneville Dam, with some Lewis River steelhead being harvested in the Columbia River catch.

Steelhead are also being caught in the commercial fisheries operating below Bonneville Dam. These fish are not sold, but released dead or alive. The incidence of delayed mortality is unknown, but it is thought to be high (Weinheimer 1992).

Based on permit-card harvest estimates, sport harvest for both North and East Fork summer steelhead (hatchery and wild) from 1980 through 1991 ranged from 3,001 steelhead in 1983-84 to 8,700 in 1986-87 (Table 2). In the past, the East Fork had the greater share of steelhead caught in the Lewis subbasin, however, average catch on the North Fork has increased since the 1970's and currently exceeds the East Fork fishery. The East Fork still remains a popular sport fishery as anglers fish for the large, wild summer steelhead which continue to propagate in this system.

Treaty Indian fishing rights are not exercised in the Lewis River subbasin.

Spawning period

Mean time of spawning occurred from January through May, peaking in February and March.

Spawning area

Spawning in the North Fork Lewis is limited with the blockage of spawning areas by Merwin Dam. Most natural spawning occurs in Cedar Creek a tributary of the North Fork. Steelhead spawn throughout most of the **mainstem** of the East Fork Lewis River as well as Rock **Creek** and other tributaries. Summer run steelhead may not ascend the numerous upstream falls in the **mainstem** as readily as winter fish (Howell et al. 1983) due to lower summer flows.

Fecundity

No data are available for Lewis River steelhead.

Age composition

No data are available for Lewis River steelhead.

Size

No data are available for Lewis River steelhead.

Sex ratio

No data are available for Lewis River steelhead.

Survival rate

No data are available for Lewis River steelhead.

JUVENILE LIFE HISTORY

Egg

Egg to smolt survival for wild summer steelhead is unknown.

Emergence

Emergence occurs from late February and runs through June.

Juvenile rearing

Juvenile rearing lasts approximately two years prior to ocean emigration, although some juveniles emigrate after one or three years (Loch et al. 1985).

Migration generally occurs from March through May with peak migration in early May. Average smolt size is estimated at 160 mm.

Hatchery releases

Currently, no steelhead hatchery operates in this **subbasin** although construction of Ariel Hatchery on the North Fork will include summer steelhead production. Summer steelhead smolts are reared in Merwin Lake net pens as part of Merwin Dam relicensing agreement. Washington Department of Wildlife releases hatchery smolts annually into the North Fork and East Fork Lewis River. Since 1979, Pacific Power and Light has reared about 60,000 additional summer steelhead smolts which are released annually into the North Fork. Table 3 outlines smolts released into the Lewis River

from 1981 to 1991.

Straying

No data on Lewis River steelhead.

BIOCHEMICAL-GENETIC CHARACTERISTICS

No data are available on Lewis River steelhead.

DISEASES

Disease history for smolts planted in the Lewis River is presented in Table 4.

REFERENCES

The references for this section appear at the end of the following steelhead section.

LEWIS -RIVER SUBBASIN

Naturally Produced Winter S tealhead

GEOGRAPHIC LOCATION

The Lewis **subbasin** begins on the southern slopes of Mount St. Helens and Mount Adams. The **mainstem** of the river is known as the North Fork Lewis River which drains a watershed of 828 square miles. From its source the North Fork flows southwest through three separate lakes, Swift Creek Reservoir, Yale Lake and Merwin Reservoir before a major tributary, East Fork Lewis River, draining a watershed of 212 square miles entering the **mainstem** at river mile (RM) 3.5. From this point the Lewis River continues west, entering the Columbia River at RM 88.

ORIGIN

The wild winter steelhead stock in the Lewis River is native, although interbreeding with introduced Cowlitz, Chambers Creek and Elochoman Hatchery stocks has likely occurred. In addition, steelhead which abandoned the **Cowlitz** system following the eruption of Mount St. Helens in 1980, probably strayed into the Lewis River and spawned with native Lewis stock.

DISTRIBUTION

Table 1 lists rearing and spawning habitat for Lewis River steelhead based on estimates from the Northwest Power Planning Council.

There are three dams (Swift, Yale, Merwin) which block passage of anadromous fish into the upper areas of the North Fork Lewis. Steelhead distribution on the North Fork occurs from approximately RM 7 to RM 20. A dam located on Cedar Creek, a tributary to the North Fork, was removed in 1946 and in combination with stream improvements spawning now occurs throughout most of Cedar Creek (Figure 1 of the prior summer steelhead section).

The East Fork Lewis River allows steelhead access and spawning throughout most of the river. Figure 2 in the prior summer steelhead section depicts wild winter and summer spawning areas in the East Fork. The lower portion of the river is becoming increasingly impacted by urbanization while the upper portion remains relatively unchanged. Prior to 1982 Sunset Falls blocked most steelhead from accessing the upper reaches of the East Fork. In 1982, the falls were "notched" lowering the falls from 13.5 ft. to 8 ft. and allowing steelhead access to the upper section of the river.

PRODUCTION

Production Facilities

There are two hatcheries in the subbasin, Lewis River Hatchery and Speelyai Hatchery. Lewis River Hatchery is located on the North Fork four miles below Merwi Dam. The hatchery is a major producer of **coho** salmon and also operates a spring chinook program. Speelyai Hatchery is located on Speelyai Creek above Merwin Dam, also on the North Fork. The hatchery rears both **coho** and spring chinook salmon.

An additional rearing facility (Ariel Hatchery) to be used for steelhead, rainbow and cutthroat trout production is planned for construction at the base of Merwin Dam. A net pen rearing system has been in operation since 1979 in Merwin Reservoir rearing 35,000 winter steelhead smolts annually for release into the North Fork Lewis River.

No data are available on wild smolt production. Natural production continues in both the North and East Fork Lewis but estimates on smolt production do not exist. The lower section of the North Fork Lewis from Merwin Dam downstream is the only section available for fish production. Merwin Dam, a 240 foot high dam, blocks upstream passage and converts the middle sections of river into three large impoundments. The East Fork provides rearing habitat throughout most of the river although access to the upper reaches are difficult due to its steep gradient with numerous drops and waterfalls.

ADULT LIFE HISTORY

Run Size and Escapement

No estimates of total run size or escapement exist for either the North or East Fork Lewis River. The Lewis basin continues to propagate a fairly large wild steelhead population. Lucas (1985) determined that the wild portion of winter steelhead at Lucia Falls ranged from 35 percent to 74 percent of fish **creeled** between 1973-1984, with an average of 56 percent wild fish.

Time of migration

Adult time of entry for winter steelhead is generally from November through May with peak returns occurring in January for hatchery fish and March for wild fish. Figure 1 depicts the freshwater life history of winter steelhead in the Lewis River subbasin.

Harvest

Ocean harvest of Lewis River winter steelhead is unknown.

The amount of Columbia River harvest of Lewis River steelhead is unknown, however, some Lewis River steelhead are likely part of the Lower Columbia harvest. Sport fishing in both the North and East Fork Lewis are popular fisheries. Catch estimates from the North Fork averaged 300 fish through the 1960's and 1970's while catches in the **1980's**, based on permit-card harvest estimates, averaged 1,577 steelhead. The East Fork sport fishery continues to attract anglers in pursuit of the large wild fish which propagate in this stream. The current state record winter steelhead (32 pounds, 12 ounces,) was caught in the East Fork in April of 1980. Total sport harvest from 1980 through 1990 for both North and East Forks averaged 4,385 (and wild; Table 2).

Treaty Indian fishing rights are not exercised in the Lewis River subbasin.

Spawning period

Spawning occurs from March through June in both North and East Forks peaking in mid-April through late May.

Spawning area

Spawning in the North Fork Lewis is limited with the blockage of upper spawning area by Merwin Dam and the three resevoirs. Most natural spawning occurs in Cedar Creek a tributary of the North Fork. Winter steelhead utilize most of the East Fork Lewis River for spawning although the upper section is more difficult to reach due to the numerous drops and falls in this section of the river.

Fecundity

No data are available for the Lewis River.

Age composition

Limited data on age composition of wild winter steelhead. From 12 wild fish sampled between 1977 through 1980 in the North Fork fishery, 17 percent were 1-ocean jacks and 83 percent were 2-ocean adults (Lavoy and Fenton 1983; Table 3). An additional study by Lavoy and Fenton (1983) in which 364 fish were sampled from the North Fork winter fishery showed the age composition as follows: 2 percent were 1-ocean fish, 63 percent were 2-ocean fish and 30 percent were 3-ocean fish plus return spawners.

Size

Table 4 lists mean fork lengths of 364 fish sampled from the North Fork winter fishery from 1977 through 1981.

Sex ratio

No data are available for Lewis River steelhead.

Survival rate

No data on smolt to adult survival.

JUVENILE LIFE HISTORY

Emergence

Emergence occurs from April and runs through July.

Juvenile rearing

Juvenile rearing lasts approximately two years prior to ocean emigration, with 83 percent emigrating after two years and 17 percent emigrating after three years (Lavoy and Fenton 1983). Most fish outmigrate from April through May. Average smolt size is estimated at 160 mm.

Hatchery releases

No winter steelhead hatchery operates in the Lewis Subbasin, although construction of Ariel Hatchery include plans for winter steelhead production. Smolt releases began in the mid 1950's with fish released into both North Fork and East Fork with current smolt releases continuing in both the North Fork and East Fork Lewis (Table 5). Smolts are reared at Beaver Creek, and Skamania hatcheries as well as Merwin Lake Net Pens.

Straying

No data on Lewis River steelhead.

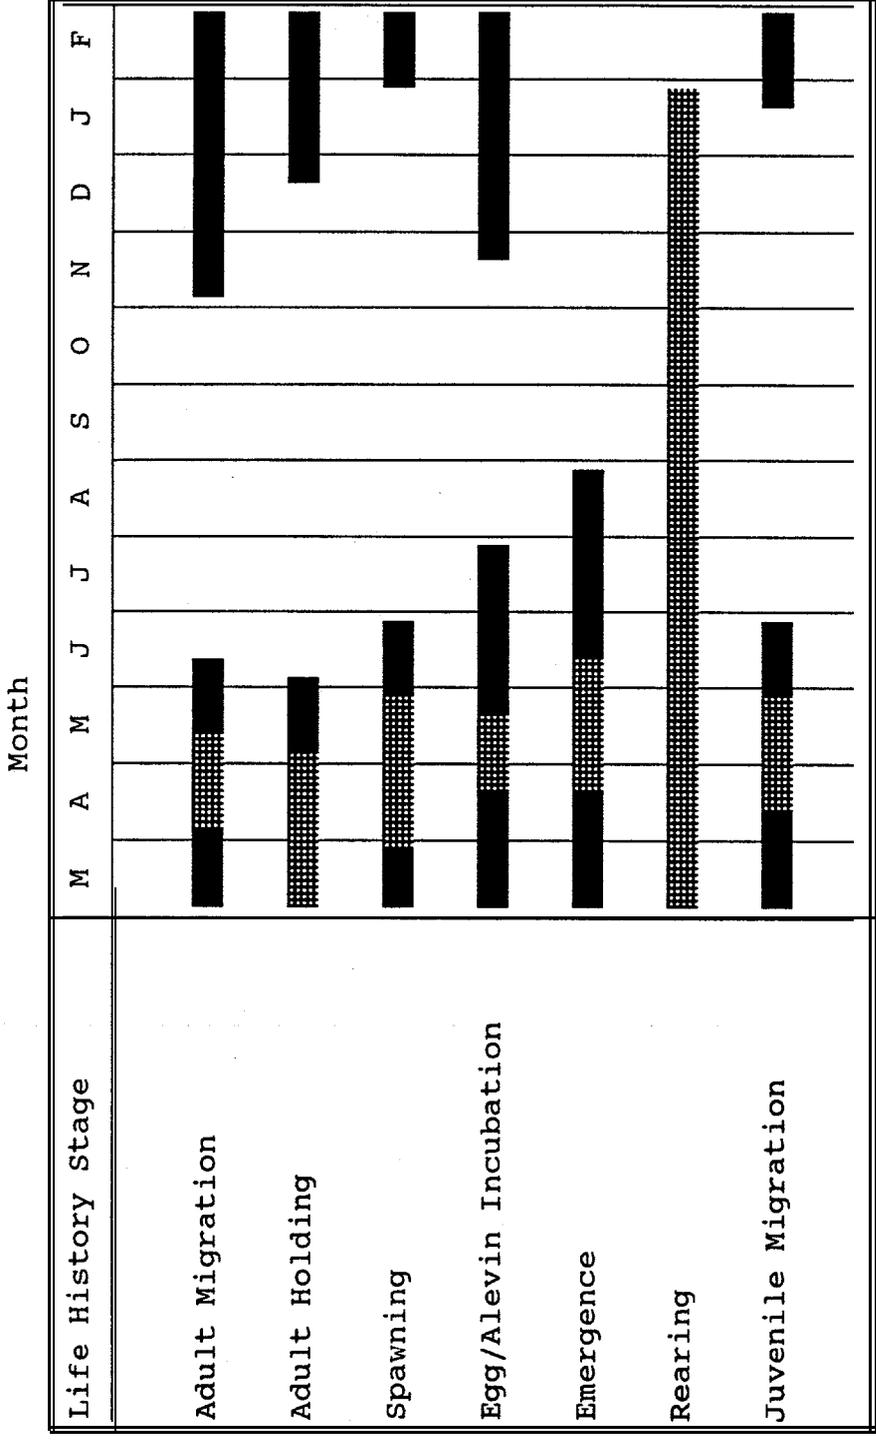

BIOCHEMICAL-GENETIC CHARACTERISTICS

No data are available for Lewis River steelhead.

DISEASES

Disease history for smolts planted in the Lewis River is presented in Table 6.

Figure 1. Freshwater life history of Lewis River winter steelhead.

▨ = Periods of heaviest activity.

Table 1 (HB-1). Estimated* amount of rearing and spawning habitat, by quality, of Lewis River **subbasin** winter steelhead.

Area	Excellent	Good	Fair ^B	Poor ^B	Unknown	Total	Confidence
Miles	38.6%	41.4%	20.3%	0 . 0 %		95.9	Unknown
Acres	42.4%	53.1%	4.8%	0.0%		673.2	Unknown

*Northwest Power Planning Council estimates based on limited observations.

*Ratings of fair and poor habitat quality may reflect natural physical features such as waterfall barriers, as well as degradation caused by man.

Viral	Beaver Creek	EIBS

^aThe Lewis River receives steelhead smolts from fish reared at Skamania Hatchery.

Disease history for the Skamania Hatchery is located in the subbasin report for the Washougal River.

^bMerwin Net Pens is a acclimating station located above Merwin Dam in Merwin Reservoir.

^cBeaver Creek Hatchery is located on the Elochoman River.

Disease history only represents pathogens isolated at the hatchery and not necessarily a disease outbreak.

WASHOUGAL SUBBASIN

Fall Chinook

GEOGRAPHIC LOCATION

The Washougal River is located in southwest Washington, originating in Skamania County and flowing southwesterly into Clark County, joining the Columbia River at River Mile (RM) 121 at the town of **Camas**. The drainage area encompasses approximately 240 square miles. The **subbasin** is relatively small compared to other major rivers entering the Columbia River. The **mainstem** Washougal runs approximately for 33 miles from headwaters to the mouth. The Washougal Hatchery is located 16 miles northeast of the town of Washougal.

ORIGIN

Native fall chinook have been reported in the Washougal (WDF, 1951), but a distinct stock no longer exists. Natural spawning does occur, but these fish are identified as hatchery strays (Devore, 1984).

Brood stock for the **Washougal** Hatchery is usually obtained from local returning stocks. However, transfers of other stocks into the system is a common practice. In recent years, such stocks as Kalama, Bonneville, Toutle, Washougal, Elochoman, and Grays River have also been imported to fill hatchery needs (WDF, 1990).

DISTRIBUTION

Washougal River fall chinook spawning ground index counts are conducted annually between the Salmon Falls Bridge at RM 15 and the Wildlife Access at RM 12, a distance of approximately 4 miles. Salmon Falls was considered a barrier to salmon migration until a fishway was constructed in the 1950s.

PRODUCTION

In 1951 the Washington Department of Fisheries estimated the fall chinook escapement to be about 3,000 fish. The number of Washougal fall chinook natural spawners each year during 1967 - 1971 was estimated to be about 550 fish (WDF, 1973). Hatchery production is currently the dominant component in the Washougal River although some natural production also occurs.

Tables 1 and 2 describe the amount of spawning and rearing habitat by quality, available in the Washougal River. This data was derived from the Presence/Absence database of Northwest Power Planning Council, 1991.

The Washougal River fall chinook natural spawn escapement from 1978 - 1984 brood years averaged 2,525 with a low return of 978 for the 1978 brood and a peak of 6,285 for the 1984 brood. Washougal River natural spawn escapements by age and brood year are presented in Table 3.

Washougal Hatchery fall chinook returns from 1978 - 1984 brood years averaged 5,822 with a low return of 1,599 for the 1978 brood and a peak of 17,471 for the 1983 brood. Washougal Hatchery returns by age and brood year are presented in Table 4.

Washougal River tributary sport catch estimates between 1977 - 1987 return years averaged 477 fall chinook, ranging from a low of 84 in 1979 to a high of 1,362 in 1987, based on punchcard data. However, specific age and brood year analysis for Washougal River sport catch is unavailable.

ADULT LIFE HISTORY

Run size, catch and escapement

Ocean commercial and recreational fisheries from Alaska to Washington, in **addition** to Columbia River gill net and sport fisheries all harvest a portion of the. **Washougal River origin** fall chinook. A **special** sport fishing area near Washougal Hatchery was established in the late **1960s** to harvest surplus fall chinook. This fishery included legal snagging and was discontinued after 1986. Columbia River sport and commercial fisheries are managed to ensure attainment of hatchery **egg-take** requirements.

Strays from other lower river hatcheries are not unusual. Table 5 lists Washougal Hatchery origin fall chinook stray coded wire tag recoveries beginning with the 1978 brood through to the 1988 brood, and Table 6 lists the coded wire tags recovered within the Washougal **subbasin** which originated outside the Washougal subbasin.

Time of Migration

Adult chinook move into the Washougal River from late September through the middle of November. Figure 1 illustrates the freshwater life history of fall chinook in the Washougal River.

Spawning Period

The holding period is relatively short with spawning occurring from the first of October through November.

Spawning Areas

Natural production occurs in the **mainstem** Washougal River downstream from the salmon hatchery. Although this includes 20 miles of stream channel, bed rock and bouldered areas result in light spawning in the stream with spawning most intensive from RM 12 - 15. Washougal River **fall** chinook spawning ground peak index counts are conducted annually between Salmon Falls Bridge and the Wildlife Access, a distance of approximately 4 miles.

Age Compositon

Age ranges from two-year-old jacks to six-year-old adults with three-year-olds or four-year-olds usually the dominant age classes. Total age composition data is summarized in Tables 3 and 4. Table 7 lists the age composition percentages by brood year and **freshwater.ocean** rearing for fall chinook returning to the Washougal River spawning grounds. Table 8 lists the age composition percentages by brood year and **freshwater.ocean** rearing for **fall** chinook returning to the Washougal Hatchery.

Sex Ratio

Female fall chinook comprised 57 - 79 percent of the natural spawners in the Washougal River between 1981 - 1984 brood years. The percent females by brood year and freshwater.ocean rearing ages for Washougal River natural spawners are presented in Table 9.

Female fall chinook comprised 25 - 47 percent of the fall chinook returning to the Washougal Hatchery between 1981 - 1984 brood years. The percent females by brood year and freshwater.ocean rearing ages for Washougal Hatchery returns are presented in Table 10. The mean fork length by brood year, sex, and freshwater.ocean rearing ages of Washougal River

natural spawners for 1978 - 1985 brood years are available in Tables 11 and 12. The mean fork length by brood year, sex, and **freshwater.ocean** rearing ages for Washougal Hatchery returns from 1978 - 1987 brood years are available in Tables 13 and 14.

Fecundity

Fecundity at the Washougal Hatchery between 1979 - 1988 return years averaged 4,354 and ranged from a low of 3,849 in 1987 to a high of 4,818 in 1981 (**WDF**, 1990). Washougal River natural spawn and Washougal Hatchery fecundity data by age and brood year is unavailable.

JUVENILE LIFE HISTORY

Time of Emergence

Incubation takes place from early October through January, with emergence sometime in February.

Time, age and size at migration

Under natural conditions, lower river hatchery chinook generally migrate downstream as subyearlings, leaving the river by late summer or fall. A small percentage of juveniles do remain in the system throughout the winter, outmigrating as yearlings (**Reimers** and Loeffel, 1967).

The number of wild juvenile fall chinook that migrated from the Washougal River in 1980 was estimated to be **5,000,000**. Population estimates are based upon comparing seining results of chinook per square feet before and after hatchery releases. Table 15 lists the number of natural juvenile fall chinook that migrated from the Washougal River in 1980.

The average natural fall chinook fork length from the Washougal River in 1980 was 49 mm. The average fork length data is based upon five biweekly seining trips to the Washougal River between May 1 - June 27, before Washougal Hatchery releases beginning on June 27th. Average fork length and ranges of 1979 brood Washougal River natural fall chinook smolts are presented in Table 16.

Hatchery release information for the Washougal **subbasin** by brood year is presented in Table 17.

Survival Rate

Egg-to-smolt survival rate from 1979 - 1988 averaged 92.5 percent (**WDF**, 1990). Washougal Hatchery 1976 brood coded wire tag (63-16-41) smolt-to-all adult survival was 1.6 percent, **smolt-to-fisheries** 1.4 percent, and from smolt-to-Columbia River 0.6 percent (Howell et al., 1985).

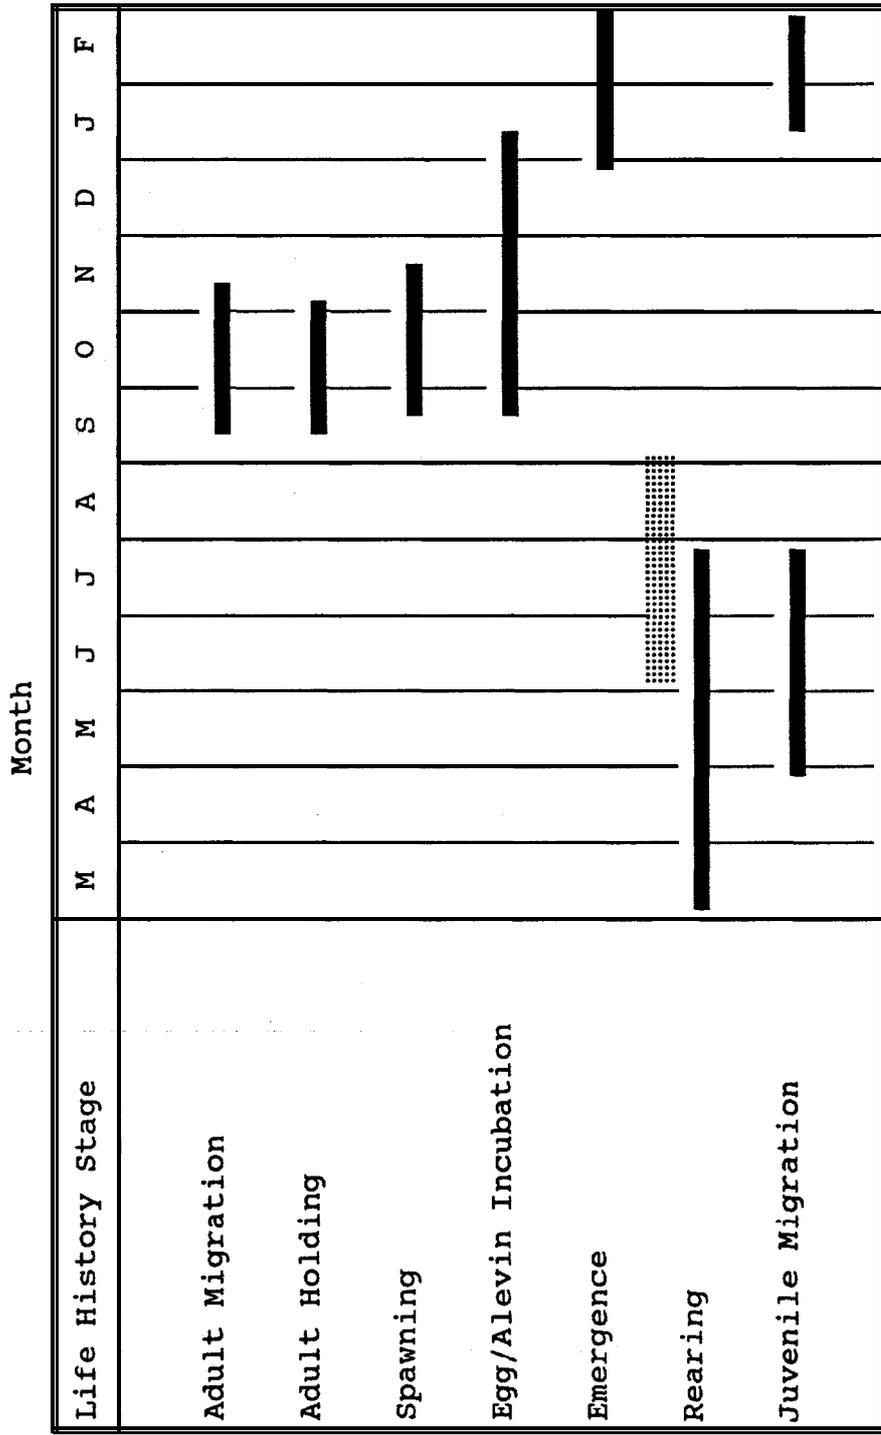

BIOCHEMICAL-GENETIC CHARACTERISTICS

Data not available.

DISEASE

Bacteria and parasitic diseases found in the Washougal Hatchery are listed in Table 18. (**WDF** Salmon Culture, Olympia).

Figure 1 (TT). Washougal fall chinook freshwater life history.

Table 15 (JM). Number of natural juvenile fall chinook that migrated from the Washougal River, 1980.

Brood Year	WDF population estimate
1979	5,000,000

Source: "Washougal River juvenile chinook observations". WDF memorandum from Hugh Fiscus to Clint Stockley, July 8, 1980. Based upon comparing seining results of chinook per square feet before and after hatchery releases.

Table 16 (SL). Lengths of fall chinook smolts from the Washougal River, 1980.

Location and year	No. Fish	Length ave. (mm)	Length range (mm)	Reference
Washougal River between River Miles 2-15.3, 1980	352	49	32-75	Various WDF memorandums May-June 1980.

Data is based upon five biweekly seining trips to the Washougal River between May 1-June 27, 1980. Not included are additional seining trips made after the Washougal Hatchery plant of fall chinook beginning June 27th. Chinook average length and ranges are based on the former seining results and may reflect rearing and/or outmigration size patterns.

WASHOUGAL SUBBASIN

Coho

GEOGRAPHIC LOCATION

The Washougal River is located in southwest Washington, originating in Skamania County and flowing southwesterly into Clark County, joining the Columbia River at River Mile (121) at the town of **Camas**. The drainage area encompasses approximately 240 square miles. The **subbasin** is relatively small compared to other major rivers entering the Columbia River. The Washougal Hatchery is located 16 miles northeast of the town of Washougal.

ORIGIN

In the Washougal River **coho** were not divided into Type-S and Type-N stocks until 1982.

Most existing early **coho** (Type-S) hatchery programs are considered to be linked to native Toutle River stock **coho**. Washington stations either received Toutle stock eggs or utilized local native early run **coho**. Late stock **coho** (Type-N) are informally considered synonymous with **Cowlitz River stock coho**. Late stock hatchery programs were developed utilizing Cowlitz River stock, their derivatives, or native late runs. Late **coho** used in most of the current programs are presumably a blend of all of these, although egg transfers from Cowlitz Hatchery occur most frequently (Howell et al. 1985).

By the time fish surveys were conducted on the Washougal River, serious habitat damage had already occurred. Due to the Yaocolt Burn, the steep hills were deforested resulting in erosion and flooding. In 1947, the Cotterell Power Company removed the last of three small hydroelectric dams which were considered low water barriers to fish migration (WDF, 1990).

In 1958, the Washougal Salmon Hatchery was completed.

DISTRIBUTION

Natural spawning occurs in most areas accessible to **coho**. On the Washougal River the heaviest natural spawning occurs in the **mainstem** between RM 12 and 15 (WDF, 1990). Natural spawning also occurs in the Little Washougal and West Fork Washougal.

PRODUCTION

In Washington and Oregon adult production of early and late **coho** from natural spawners is unquantified except for a few instances. A factor of 10 - 15 percent might be considered reasonable for the percent of the total Columbia River **coho** production originating from naturally spawning fish (Howell et al. 1985). Hatchery production is the dominant component in the Washougal River although some natural production also occurs.

Tables 1 and 2 describe the amount of spawning and rearing habitat, by quality, available in the Washougal River. This data was derived from the Presence/Absence database of the Northwest Power Planning Council, 1991.

Washougal River tributary sport catch estimates between 1979 - 1986 return years averaged 924 adult **coho**, and ranged from a low of 172 in 1983 to a high of 2,629 in 1986. These estimates were based on catch records and limited actual sampling data. However, specific

age and brood year analysis for Washougal River sport catch is unavailable.

The number of Washougal River **coho** natural spawn escapement is unavailable. Washougal River Hatchery returns from the 1979 -1988 brood years of Type-S **coho** averaged 5,740 with a low of 551 in 1984 and a peak of 16,999 in 1983. Hatchery returns of Type-N **coho** for the 1979 - 1988 brood year averaged 5,296 with a low of 2,743 in 1985 and a high of 10,443 in 1986. Hatchery returns by age and brood year for early and late **coho** are presented in Tables 3 and 4, respectively.

An additional special snag fishery of excess **coho** was once present on the Washougal River near the hatchery. The last full season of the fishery was in 1986 with a partial season of three days in 1987 due to the fact no substantial catch was available. Harvest rates for the 1979 - 1986 snag fishery averaged 1,193 adults with a low of 325 in 1979 and a high of 3,073 in 1982 based on catch records and limited sampling.

ADULT LIFE HISTORY

Run size, catch and escapement

Ocean commercial and recreational fisheries off the Oregon coast are the primary harvesters of early **coho**. The Oregon troll fishery accounts for the highest percentage of the overall catch. Most of the freshwater recreational harvest occurs in the Washington tributaries (Howell et al. 1985).

Based on coded-wire tagged releases of 1976 - 1978 brood late **coho**, most of the harvest occurs in the Washington and Oregon ocean fisheries. Late **coho** have a more northerly migration pattern than early **coho** (WDF, 1990). This is reflected in the catch distribution where the Washington coastal catch comprised 40 percent of the total harvest compared to 20 percent for early **coho** during 1979 - 1981. Late **coho** also contribute significantly to the lower Columbia River commercial gill net fishery (Howell et al. 1985).

Strays from other lower river hatcheries are not unusual. Table 5 lists coded-wire tagged **coho** from the Washougal Hatchery which were recovered by non-harvest means outside of the subbasin, beginning with the 1978 brood, and ending with the 1988 brood. Coded-wire tags which originated outside the Washougal **subbasin** but were recovered within the Washougal **subbasin** are listed in Table 6.

In 1934 **coho** salmon in the Washougal had the first good run in 22 years (WDF, 1990). In 1951, **coho** escapement was estimated at 3,000 fish. By 1973 the largest salmon run was early stock hatchery **coho** (WDF, 1990).

Harvest rates have averaged 79 percent and 85 percent for Type-S and N stocks, respectively, between 1983 and 1987. Harvest of Type-S **coho** is occasionally constrained by one or more of the fall chinook stocks. Harvest of Type-N **coho** is generally not constrained by weak stocks, with hatchery escapement being the only management constraint (WDF, 1990).

Time of Migration

Early **coho** enter the Columbia River by mid-August and begin returning to the lower Columbia hatcheries in early September. In the **mainstem** Columbia River early **coho** predominate from August to mid-September. Stock composition shifts to late **coho** in late September and October. Typically, the late **coho** run begins entering freshwater in mid to late September with mid-October considered the main migratory period in the **mainstem**

Columbia River (Howell et al. 1985).

Spawning Period

For Type-S **coho**, both hatchery and natural spawning occurs around late October, while for Type-N **coho** spawning will extend from late November through March, with the bulk being in December and early January (Howell et al. 1985).

Spawning Areas

Natural spawning occurs in most areas accessible to **coho**.

Age composition

Coho return as two-year-old jacks and three-year-old adults. The age composition of the late **coho** run entering the Columbia River is not available because of incomplete escapement information and the differential trapping of adults and jacks at many collection facilities (Howell et al. 1985). Specific age composition percentage (freshwater.ocean) by brood year for **coho** spawning naturally and hatchery returns are unavailable.

Sex Ratio

Accounting for the differential harvest of adult males and females in the gill net fishery, the adult run entering the Columbia River was estimated to be 46 percent females in 1982 and 30 percent females in 1983. Hatchery adult returns were 33 percent females in 1982 and 34 percent females in 1983 (Howell et al. 1985). The percent of Type-S **coho** females for the 1982 - 1988 return years averaged 38 percent with a low return of 30 percent in 1987 and a high of 74 percent in 1986 (WDF, 1990). The percent of Type-N **coho** females for the 1982 - 1988 return years averaged 27 percent with a low return of 21 percent in 1986 and a high of 37 percent in 1985 (WDF, 1990). Specific percent females by brood year and age class (freshwater.ocean) for **coho** spawning naturally and hatchery returns are unavailable.

Fecundity

Type-S stock **coho** fecundity at the Washougal Hatchery for 1982 - 1988 return years averaged 2,331, with a low of 1,977 in 1988 and a high of 2,755 in 1985.

Type-N stock **coho** fecundity at the Washougal Hatchery for 1982 - 1988 return years averaged 2,446 and ranged from a low of 1,863 in 1989 to a high of 2,736 in 1982.

Washougal River natural spawn and Washougal Hatchery fecundities by brood year and age class are unavailable.

JUVENILE LIFE HISTORY

Time of Emergence

The juvenile life history for Washougal **subbasin coho** is similar to that of other stocks in the region with a spring emergence (WDF, 1990).

Time, age and size at migration

Freshwater rearing generally lasts for about 14 months. Hatchery release information for the Washougal **subbasin** by brood year is presented in Table 7. Based on coded-wire tag recovery studies by Dawley et al. (1982), arrival in the Columbia River estuary occurs soon

after hatchery release (Howell et al. 1985). Length data of natural **coho** smolts from the Washougal River is unavailable. The number of natural juvenile **coho** salmon that migrate from the Washougal River is also unavailable.

Survival Rate

A generalized recent year smolt to adult survival rate for **coho** was estimated to be 2.5 percent (**TAC** 1983) (Howell et al. 1985). Type-S stock **coho** egg to smolt survival at the Washougal Hatchery for the 1979 - 1986 return years averaged 80 percent with a low of 38 percent in 1984 and a high of 91 percent in 1980 and 1985 (**WDF**, 1990).

Type-N stock **coho** egg to smolt survival at the Washougal Hatchery for the 1982 - 1986 return years averaged 86 percent with a low of 83 percent in 1985 and a high of 89 percent for 1984 (**WDF**, 1990).

BIOCHEMICAL-GENETIC CHARACTERISTICS

Data has not been compiled.

DISEASE

Bacteria and parasitic diseases found in the Washougal Hatchery are listed in Table 8. (**WDF** Salmon Culture, Olympia).

Table 1 (HB-1). Estimated amount of rearing and spawning habitat, by quality, of the Washougal River **coho** production area.

Distance/Area	Excellent	Good	Fair ^a	Poor ^a	Unknown	Total	Confidence
Miles (%)	43	53	04	00		23.2	
Acres (%)	54	43	02	00		44.4	

^a Ratings of fair and poor habitat quality may reflect natural physical features such as waterfall barriers, as well as degradation caused by humans.

WASHOUGAL RIVER SUBBASIN

Naturally Produced Summer Steelhead

GEOGRAPHIC LOCATION

The Washougal River is located in southwest Washington, within Skamania and Clark counties. From its headwaters the Washougal River flows southwesterly approximately 33 miles joining the Columbia River at river mile (RM) 121 near the town of **Camas**. Along its course numerous tributaries join the **mainstem** with the largest being the West Fork Washougal, Little Washougal, Stebbins Creek and Cougar Creek. Total drainage area encompasses approximately 240 square miles.

ORIGIN

The summer steelhead stock in the Washougal River is indigenous, although interbreeding with introduced Skamania and Cowlitz hatchery stocks has probably occurred. In addition, steelhead which abandoned the Cowlitz system following the eruption of Mount St. Helens in 1980, may have strayed into the Washougal River and spawned with native Washougal stock.

DISTRIBUTION

Table 1 lists spawning and rearing habitat, by quality, for Washougal River steelhead based on estimates from the Northwest Power Planning Council.

Summer steelhead are distributed throughout the **mainstem** Washougal River including the tributaries of the West Fork Washougal, Little Washougal River and Stebbins and Cougar creeks (Figure 1). **Dougan** Falls located at RM 21 is considered a low water barrier to steelhead. Above **Dougan** Falls the stream gradient increases with numerous falls and cascades which limit the number of fish that can access the upper section of river.

PRODUCTION

Production Facilities

There are two hatcheries in the subbasin, the Washougal Hatchery located on the **mainstem** Washougal River 16 miles northeast of the town of Washougal and the Skamania Hatchery located on the North Fork Washougal River. The Washougal Hatchery is operated by Washington Department of Fisheries and is a major producer of **coho** and chinook salmon. Skamania Hatchery is operated by Washington Department of Wildlife and produces summer and winter steelhead.

Production Summary

No data is available on wild smolt production. Production has fluctuated widely due to a number of natural events and human activities including; gravel mining on the lower 20 miles of river which stripped the lower river of most of its spawning gravel, pollution from a pulp mill which releases its effluent near the mouth of the river, logging in the upper watershed, and earlier this century forest fires which occurred in the upper subbasin. In an effort to increase production, several small dams which blocked or impeded fish passage have been removed or by-passed **allowing** steelhead access to more of both the **mainstem** Washougal River and several tributaries.

ADULT LIFE HISTORY

Run Size and Escapement

Steelhead run size and escapement between 1925 and 1933 was estimated at 2,500 fish. In 1935, steelhead were believed to be the largest fish run in the Washougal River at which time investigators counted 539 steelhead below **Dougan** Falls (Bryant 1949). In 1953, spawning surveys began on the Washougal River which resulted in estimates of 500 wild fish. **Schuck** (1980) estimated a total run of 4,268 summer steelhead (hatchery and wild) returning to the Washougal in 1979 although the wild portion of the run was estimated at only 268 fish or 6.6 percent. Average total run size (hatchery and wild) from 1964 through 1984 was 2,525 steelhead with the exact numbers of wild fish not known but believed to be very low (Subbasin Plan 1990).

Time of migration

Angling data collected between 1971 and 1984 show that wild adult summer steelhead enter the Washougal **subbasin** between March and November, with two distinct peaks. About 38 percent of the fish return between March and July with the remaining 68 percent of the fish entering the **subbasin** from August through November. Figure 2 illustrates the freshwater life history of summer steelhead in the Washougal River.

Harvest

Ocean catch of Washougal River steelhead are unknown.

The number of Washougal River steelhead caught in the Columbia River is unknown. However, large numbers of steelhead are harvested in the Columbia River including

Based on permit-card harvest estimates, sport catch ranged from 272 fish in the 1964-1965 season to a high of **5,699^A** fish in the 1989-1990 season. Average annual sport catch from 1983 through 1990 was at 1,560 fish (Table 2). As of 1986, fishing regulations allow legal harvest of hatchery fish only, with mandatory release of wild steelhead.

Treaty Indian harvest does not occur in the Washougal **Subbasin** or below Bonneville Dam on the Columbia River.

Spawning period

Spawning occurs from January through April, peaking in February and March (Howell et al. 1985).

Spawning area

Spawning occurs in the **mainstem** Washougal River, the West Fork Washougal and in the tributaries of Stebbins and Cougar creeks and the Little Washougal River.

Fecundity

No data is available for Washougal steelhead.

^ASport catch 1981-1982 may be biased due to steelhead straying from eruption of Mount St. Helms.

Age Composition

Limited data on Washougal summer steelhead age composition. Based on 7 wild steelhead sampled from a 1979 creel census, 14.3 percent were from age class 2.1, 71.4 percent were from age class 2.2 and 14.3 percent were from age class 2.3.

Size

Fork lengths from 7 wild steelhead sampled from creel census showed average length of 2.1, 2.2 and 2.3 age class fish were 57 cm, 76 cm and 97 cm, respectively.

Sex ratio

Sex ratio for the 7 wild steelhead sampled in 1979 was four males and three females.

Survival Rate

No data is available for Washougal steelhead.

JUVENILE LIFE HISTORY

Egg

No data is available on egg production or egg to smolt survival.

Emergence

Wild steelhead fry emerge March through May (Subbasin Plan, 1990).

Juvenile rearing

Juvenile rearing lasts approximately two years prior to ocean emigration.

Juvenile steelhead outmigration generally occurs from April through May at an average size of 160 mm.

Hatchery Releases

The Washougal River receives hatchery smolts from the Skamania Hatchery which is located on the Washougal River. Hatchery releases into the Washougal River and data associated with Skamania hatchery stock is listed in the adjoining Washougal River hatchery summer steelhead report.

Straying

No data on Washougal steelhead.

BIOCHEMICAL-GENETIC CHARACTERISTICS

No data is available on Washougal steelhead.

DISEASES

Disease history for smolts planted in the Washougal River is presented in the adjoining Washougal River hatchery summer steelhead report.

WASHOUGAL RIVER SUBBASIN

Skamania Hatchery Summer Steelhead

GEOGRAPHIC LOCATION

Skamania Hatchery is located on the North Fork Washougal River approximately one mile upstream from the confluence of the North Fork Washougal and the **mainstem** Washougal River and approximately 12 miles from the mouth of the **mainstem** Washougal River.

ORIGIN

The Skamania summer steelhead broodstock was developed in the late 1950's at the Skamania Hatchery. Skamania broodstock were originally developed from native Washougal and Klickitat River steelhead.

PRODUCTION

Production Facilities

Skamania hatchery is a major producer of summer and winter steelhead but also rears sea run cutthroat trout. Rearing areas consist of 32 **10ft** x 80ft raceways and 3 12ft x **100ft** adult holding raceways. Incubation is by vertical stacks and hatchery troughs. Water from the Washougal River is used for all rearing except egg incubation where water is supplied from Vogel Creek (virus free water supply) a tributary to the North Fork Washougal River.

Production Summary

Skamania steelhead are artificially propagated in a hatchery environment. Skamania Hatchery annually produces approximately 800,000 smolts (summer and winter). Current summer production (1992) is approximately 340,000 smolts. Progeny of fish spawned at Skamania Hatchery are also reared at Beaver Creek and Vancouver hatcheries. Currently, **Skamania** Hatchery supplies **Ringold** Springs Rearing Ponds (located on the mid Columbia River above **Tri-cities**, Washington) with steelhead fry for grow-out and release.

ADULT LIFE HISTORY

Run Size and Escapement

Steelhead run size from 1970 through 1981, based on sport catch and hatchery returns, ranged from as low of 1,803 steelhead in 1983 to a high of 13,567 fish in 1990 (Table 1).

Time of migration

Steelhead first enter the Columbia River between mid-June and mid-July (based on angling data from the lower Columbia River which showed Skamania steelhead being harvested by sport anglers primarily between mid-June and mid-July). Skamania steelhead smolts released into the Kalama River returned to the river from mid-March through early February, peaking in June and July. Skamania steelhead return to the Skamania Hatchery primarily from May through October, peaking in June and July.

Harvest

Ocean catch of Skamania Hatchery steelhead are unknown.

The Columbia River commercial fisheries catch large numbers of **steelhead** and although the exact number of Skamania steelhead caught is not known, some Skamania hatchery fish are likely part of the Columbia River harvest.

Based on permit-card harvest estimates, sport catch from 1960 through 1990 ranged from 272 fish in the 1964-1965 to 5,042 in 1981-1982. Average annual sport catch from 1983 through 1990 was 1,560 fish. Table 1 outlines yearly sport catch from 1970 through 1989. As of 1986, fishing regulations allow legal harvest to hatchery fish only, with mandatory release of wild steelhead.

Spawning period

Spawning occurs from mid-December through February.

Spawning area

Spawning occurs at the Skamania Hatchery.

Fecundity

Skamania females spawned at Skamania Hatchery from 1976 through 1983 yielded an average of 4,024 eggs each (Table 2).

Age Composition

Age structure for Skamania summer steelhead is predominantly **2-ocean** fish, with Skamania stock returning to the Skamania Hatchery and the Kalama and Klickitat Rivers, averaging **82.8%**, 86.4% and 91.8% for **2-ocean** fish, respectively (Tables 3, 4 and 5). Repeat spawners comprised an average of 3.6% of the Skamania stock returning to the Kalama River and 1.4 % for Klickitat River (Howell et al. 1985).

Size

Mean fork lengths for 2-ocean fish returning to the Kalama River between 1976 and 1979 was 73.5 cm, while 2-ocean fish returning to the Klickitat River in 1979 through 1980 averaged 71.8 cm (Howell et al. 1985). Fork lengths for individual classes for Skamania steelhead returning to the Kalama and Klickitat rivers is presented in Table 6.

Sex ratio

Sex ratio for Skamania steelhead returning to the Kalama and Klickitat Rivers between 1976 and 1980 ranged from a low of 42.5% females in 1978 to a high of 66.5% females in 1980 (Table 7).

Survival Rate

Smolt to adult returns, based on twelve years of data from 1970 through 1982, for Skamania steelhead returning to Skamania Hatchery ranged from a low of 2.3 percent return in 1973, to a high of 6.9 percent in 1981 (Table 8).

JUVENILE LIFE HISTORY

Egg

Egg production (total hatchery egg take) for the eight year period 1976 through 1983 averaged **4,169,375** eggs annually (Table 2). Egg to smolt survival rates for Skamania **steelhead** spawned at Skamania Hatchery average approximately 75-80 percent in-the absence of major disease outbreaks (Howell et al. 1985).

Juvenile rearing

Skamania steelhead smolts are typically reared to 1-year old fish at which time they are released at a size of 4-7 fish per pound (**65-** 114 grams each). Skamania smolts are generally released in April and May with outmigration following shortly after release. Skamania smolts released into the Klickitat and Wind Rivers from April 17-30, 1980 were recovered in the Columbia River estuary from April 30 through June 3, with a median recapture date of May 10 (**Dawley** et al. 1982). Outmigration of Skamania smolts released into the Kalama occurs within a week of release, with residualism until the following October at approximately 0.3 - 1.2 percent (Howell et al. 1985).

Hatchery Releases

Skamania Hatchery smolt releases into the Washougal River are listed in Table 9.

Since 1970, Skamania smolts have been released into the following Washington streams, all of which drain into the Columbia River: Elochoman River, Toutle River (tributary to the Cowlitz), Kalama River, Lewis River (North and East Fork), Washougal River, Wind River, Big White Salmon River, Klickitat River, **Walla Walla** River, Snake River, Tucannon River, Grande Ronde River, Yakima River, **mainstem** Columbia River, Crab Creek, and the Wenatchee River. In addition, Skamania smolts have been transferred to the states of Oregon, Idaho, California, Indiana, Rhode Island, Vermont, Pennsylvania, South Carolina and North Carolina and the countries of Ireland and Korea (Howell et al. 1985).

Straying.

No data is available on Skamania steelhead.

BIOCHEMICAL-GENETIC CHARACTERISTICS

Thorgaard (1977) reported that Skamania steelhead had 58 chromosomes.

DISEASES

The major disease afflicting Skamania hatchery-stock steelhead has been infectious hematopoietic necrosis (**IHN**). Disease history, outlining all pathogens detected at Skamania Hatchery, for smolts reared at the Skamania Hatchery on the Washougal River is presented in Table 10.

REFERENCES

The references for this section appear at the end of the Skamania winter steelhead section.

WASHOUGAL RIVER SUBBASIN

Naturally Produced Winter Steelhead

GEOGRAPHIC LOCATION

The Washougal River is located in southwest Washington, within Skamania and Clark counties. From its headwaters the Washougal River flows southwesterly approximately 33 miles entering the Columbia River at river mile (RM) 121 near the town of **Camas**. Major tributaries include the West Fork Washougal, Little Washougal, Stebbins Creek and Cougar Creek. Total drainage area encompasses approximately 240 square miles.

ORIGIN

The winter steelhead stock in the Washougal River is indigenous, although some genetic influence has probably been exerted by introduced Chambers Creek, Cowlitz and Elochoman hatchery-stock steelhead. In addition, steelhead which abandoned the Cowlitz system following the eruption of Mount St. Helens in 1980, may have strayed into the Washougal River and spawned with native Washougal stock.

DISTRIBUTION

Table 1 lists spawning and rearing habitat, by quality, for Washougal River steelhead based on estimates from the Northwest Power Planning Council. Winter steelhead are distributed throughout the **mainstem** Washougal River including the tributaries of the West Fork Washougal, Little Washougal River and Stebbins and Cougar creeks (Figure 1 of the first Washougal summer steelhead section). **Dougan** Falls located at RM 21 is considered a low water barrier to steelhead. Above **Dougan** Falls the stream gradient increases with numerous falls and cascades which limit the number of fish that can access the upper section of river.

PRODUCTION

Production Facilities

There are two hatcheries in the subbasin, the Washougal Hatchery located on the **mainstem** Washougal River 16 miles northeast of the town of Washougal and the Skamania Hatchery located on the North Fork Washougal River. The Washougal Hatchery is operated by Washington Department of Fisheries and is a major producer of **coho** and chinook salmon. Skamania Hatchery is operated by the Washington Department of Wildlife and produces summer and winter steelhead.

Production Summary

No data is available on wild smolt production although winter steelhead production is considered low. Production constraints would include gravel mining on the lower 20 miles of river, continued urbanization of the watershed which has created runoff fluctuations resulting in unstable stream flows, pollution from a pulp mill which releases its effluent near the mouth of the river and logging and forest fires which occurred earlier this century in the upper subbasin.

ADULT LIFE HISTORY

Run Size and Escapement

No data is available on wild winter steelhead run size or escapement. An interim escapement goal of 630 fish has been established for this stock.

Time of migration

Wild winter steelhead enter the Washougal River from January through May, peaking in March. The freshwater life history of winter steelhead in the Washougal River is illustrated in Figure 1.

Harvest

Ocean catch of Washougal River winter steelhead are unknown.

The Columbia River fisheries catch large numbers of steelhead and although the exact number of Washougal River steelhead caught is not known, some Washougal fish are **likely** part of the Columbia River harvest.

Based on permit-card harvest estimates, sport catch of winter steelhead from 1980 through 1990 ranged from 1,377 fish in 1982-1983 to 3,195 fish in 1984-1985 (Table 2). As of 1986, fishing regulations permit legal harvest to hatchery fish only, with mandatory release of wild steelhead.

Treaty Indian harvest does not occur in the Washougal subbasin.

Spawning period

Spawning occurs from March through June.

Spawning area

Wild winter steelhead spawn in the **mainstem** Washougal, the -West Fork Washougal and the Little Washougal Rivers and the tributaries of Stebbins and Cougar Creeks.

Fecundity

No data is available on Washougal steelhead.

Age Composition

No data is available on Washougal steelhead.

Size

No data is available on Washougal steelhead.

Sex ratio

No data is available on Washougal **steelhead**.

Survival Rate

No data is available on Washougal steelhead.

JUVENILE LIFE HISTORY

Egg

No data is available on egg production or egg to smolt survival.

Emergence

No data is available on Washougal steelhead.

Juvenile rearing

Juvenile rearing lasts approximately two years prior to ocean emigration. Juvenile steelhead outmigration generally occurs from April through May.

Hatchery Releases

The Washougal River receives hatchery smolts from the Skamania Hatchery which is located on the Washougal River. Hatchery releases into the Washougal River and associated data concerning the Skamania Hatchery stock is listed in the adjoining Washougal River hatchery produced winter steelhead report.

Straying

No data is available on Washougal steelhead.

BIOCHEMICAL-GENETIC CHARACTERISTICS

No data is available on Washougal steelhead.

DISEASES

No data is available on wild Washougal steelhead.

WASHOUGAL RIVER SUBBASIN

Skamania Hatchery Winter Steelhead

GEOGRAPHIC LOCATION

Skamania Hatchery is located on the North Fork Washougal River approximately one mile upstream from the confluence of the North Fork Washougal and the **mainstem** Washougal River and approximately 12 miles from the mouth of the **mainstem** Washougal River.

ORIGIN

The **Skamania** winter steelhead broodstock was developed from predominantly Elochoman and Cowlitz hatchery-stock steelhead with some native Washougal winter steelhead included in the breeding program.

PRODUCTION

Production Facilities

Skamania Hatchery is a major producer of summer and winter steelhead but also rears sea run cutthroat trout. Rearing areas consist of 32 **10ft x 80ft** raceways and 3 adult holding raceways 12ft x **100ft**. Incubation is by vertical stacks and hatchery troughs. Water from the Washougal River is used for **all** rearing except egg incubation where water is supplied from Vogel Creek (virus free water supply) a tributary to the North Fork Washougal River..

Production Summary

Skamania steelhead are artificially propagated in a hatchery environment. Skamania Hatchery produces approximately **800,000** (summer and winter) smolts annually. Current production (1992) of winter steelhead is approximately 260,000 smolts. Progeny of fish spawned at Skamania Hatchery are also reared at Beaver Creek and Vancouver hatcheries.

ADULT LIFE HISTORY

Run Size and Escapement

No data is available on Skamania steelhead.

Time of migration

Skamania hatchery-stock steelhead return to Skamania Hatchery from December through March. From 296 steelhead returning to Skamania Hatchery in 1982-83, 11.4% arrived in December, 46.9% arrived in January, 35.8% arrived in February, 5.4% arrived in March and **.3%** (1 fish) arrived in April.

Harvest

Ocean catch of Skamania Hatchery **steelhead** are unknown.

Large numbers of steelhead are harvested from the Columbia River and although the exact number of Skamania steelhead caught is not known, some Skamania hatchery fish are likely part of the Columbia River harvest.

Based on permit-card harvest estimates, sport catch from 1980 through 1990 ranged from 1,377 fish in 1982-83 to 3,195 fish in 1984-85. Average sport catch for the past ten seasons was estimated at 2,107 fish (Table 1). As of 1986, fishing regulations permit legal harvest to hatchery fish only, with mandatory release of wild steelhead.

Spawning period

Spawning occurs from mid-January through February. From 296 fish returning to Skamania Hatchery in 1982-83, winter steelhead were spawned January 13 through February 24.

Spawning Area

Spawning occurs at the Skamania Hatchery.

Fecundity

Limited data of fecundity. Skamania females spawned at Skamania Hatchery in 1983 yielded an average of 4,688 each (Table 2).

Age Composition

No data on age structure for Skamania winter steelhead.

Size

No data is available for Skamania winter steelhead.

Sex ratio

No data is available on Skamania winter steelhead.

Survival Rate

No data is available on Skamania winter steelhead.

JUVENILE LIFE HISTORY

Egg

No data is available on Skamania winter steelhead.

Juvenile rearing

Skamania steelhead **smolts** are typically reared to 1-year old fish at which time they are released at a size of 4-7 fish per pound (65-114 grams each). Skamania Smolts are generally released in April and May.

Hatchery Releases

Skamania Hatchery smolt releases into the Washougal River are listed in Table 3.

Straying

No data is available on Skamania steelhead.

BIOCHEMICAL-GENETIC CHARACTERISTICS

No data is available on **Skamania** steelhead.

DISEASES

The major disease afflicting Skamania hatchery-stock **steelhead** have been infectious hematopoietic necrosis (**IHN**). Disease history, outlining all pathogens detected at Skamania Hatchery for smolts reared at the Skamania Hatchery on the Washougal River is presented in Table 4.

WIND RIVER SUBBASIN

Spring Chinook

GEOGRAPHIC LOCATION

The Wind River is located in southwestern Washington and enters the Columbia River above Bonneville Dam at River Mile (RM) 154.5. The Wind River is about 30.5 miles long, drains about 225 square miles and lies within Skamania County. Much of the **subbasin** is within the Gifford Pinchot National Forest. Carson National Fish Hatchery is located at **Tyee Springs** (RM 18).

An Indian "in-lieu" fishing site has been set aside at the Wind River mouth in compensation for tribal fishing grounds inundated by Bonneville Dam.

ORIGIN

Historically, Shipperd Falls at RM 2 is a series of falls approximately 40 feet high that blocked spring chinook migration. Fulton (1968) indicated spring chinook spawning habitat was absent below the falls and a native run did not exist.

The Wind River spring chinook are managed as a hatchery stock. Carson National Fish Hatchery was constructed in 1938. Several early attempts were made to introduce spring chinook into the Wind River. From 1938 - 1940 between 91,700 to 96,500 fish were released. The first three groups of fish were eggs from spring chinook taken from the Clackamas River in Oregon. Incubation and rearing of all groups was at Carson Hatchery. Apparently those efforts were not successful, as no fish were observed returning as adults. The 7,600 fingerlings released in 1953 were from eggs provided by a Willamette River hatchery operated by the Fish Commission of Oregon; however attempts were again unsuccessful (Zimmer, Wahle, and Maltzoff, 1963). In 1945, an experimental transfer of 35,382 eggs from the Salmon River in Idaho was used to determine the feasibility of a full production program which was scheduled to begin in 1951 (WDF, 1951).

In 1955, agencies of the Columbia River Fishery Development Program began a program to introduce spring chinook to the Wind River. The program consisted of 1) construction of a ladder at Shipperd Falls, 2) transfer of adult spring chinook to Carson National Fish Hatchery and 3) rearing and releasing juvenile spring chinook into the Columbia River (WDW, 1990). The program eventually began in 1958 and 1959 using spring chinook collected at Bonneville Dam for broodstock. The release of **1,016,500** yearlings in 1960 and 260,700 yearlings in 1961 provided the basis for establishment of a permanent program at Carson Hatchery (Howell et al. 1985).

DISTRIBUTION

In 1956, Shipperd Falls were **laddered** permitting salmon access to the upper areas. The principal spawning area in the Wind River is from the mouth of Paradise Creek at RM 25 downstream approximately 10 miles.

PRODUCTION

Hatchery production is the dominant component in the Wind River although some natural production also occurs.

Tables 1 and 2 describe the amount of spawning and rearing habitat by quality, available in the Wind River. This data was derived from the Presence/Absence database of Northwest Power Planning Council, 1991.

Carrying capacity was estimated at 157,533 **smolts** based on the Northwest Power Planning Council's model. However, spring chinook production may be limited by steep gradients and low summer flows.

The Wind River spring chinook natural spawn escapement from **1970** - 1990 return years averaged 305 with a low of 80 in 1982 and a peak of 2,352 in 1971. **Wind** River natural escapement by age and brood year is currently unavailable.

Carson Hatchery spring chinook returns from 1967 - 1984 brood years averaged 3,344 with a low of 222 for the 1972 brood and a peak of 9,939 for the 1971 brood. Carson Hatchery returns by age and brood year are presented in Table 3.

Wind River tributary sport catch estimates between 1967 - 1989 brood years excluding 1977 - 1980 averaged 898 with only 1 caught for the 1976 brood and a peak catch of 2,859 for the 1973 brood. Wind River tributary sport catches by age and brood year is listed in Table 4.

Wind River spring chinook tribal harvest from 1987 and 1990 return years were 9 and 29 fish, respectively. Wind River tribal harvest by age and brood year is currently unavailable.

Carson Hatchery spring chinook tribal donations from 1986, 1987, and 1990 return years were 1,408, 617, and 7,691 fish, respectively. Carson Hatchery tribal donations by age and brood year is currently unavailable.

The Wind River spring chinook total returns from 1968 - 1984 return years averaged 4,246 with a low of 265 in 1972 and a peak of 12,717 in 1971. Wind River total returns by age and brood year is currently unavailable.

ADULT LIFE HISTORY

Run size, catch and escapement

Ocean commercial and recreational fisheries from Alaska to Washington, in addition to Columbia River gill net and sport fisheries all harvest a portion of the Wind River origin spring chinook. **Out-**of-subbasin harvest which includes ocean and Columbia River harvests has averaged about 15 percent (**WDW**, 1990). Based on tag recoveries and genetic stock identification studies, most Carson spring chinook harvest occurs in freshwater. When Carson Hatchery is expected to achieve its escapement goal, the Washington Department of Fisheries and the Yakima Indian Nation develop a harvest plan for sharing the harvestable surplus between the recreational fishery and the Yakima tribal members. Since 1970, sport fisheries have occurred annually except between 1980 - 1985. The **subbasin** recreational harvest rate averaged 20.8 percent from 1970 - 1990 return years excluding 1980 - 1985 (**LeFleur** and Pettit, 1991). Columbia River sport and commercial fisheries are managed to ensure attainment of hatchery egg-take requirements while minimizing other upriver stock impacts.

Strays from other hatcheries are relatively uncommon. Table 5 lists Carson Hatchery origin spring chinook stray coded wire tag recoveries beginning with the 1978 brood through to the 1988 brood, and Table 6 lists the coded wire tags recovered within the Wind River **subbasin** which originated outside the Wind River subbasin.

Time of Migration

Spring chinook destined for areas upstream of Bonneville Dam begin entering the Columbia River in large numbers in mid-March. Counts peak at Bonneville Dam usually between April 20 and April 28 but can be earlier during abnormally low flow years or later during high run-off. Adults return to the **subbasin** from mid-May to mid-August (Howell et al., 1985).

Spawning Period

Peak of natural spawning in the Wind River occurs during the latter part of August. At Carson Hatchery, spawning commences about August 10 and can extend to about September 7 (Howell et al., 1985).

Spawning Areas

The principle spawning area in the Wind River is from the mouth of Paradise Creek downstream approximately 10 miles.

Age Comuosition

Age ranges from three-year-old jacks to six-year-old adults with four-year-olds or five-year-olds usually the dominant age classes. Total age composition data is summarized in Tables 3 and 4. Table 7 lists the age composition percentages by brood year for spring chinook returning to the Carson Hatchery. The age composition percentages by brood year for spring chinook returning to Wind River spawning grounds is currently unavailable.

The mean fork length by brood year, sex, and freshwater.ocean rearing ages for Carson Hatchery from 1977 - 1987 brood years are available in Tables 9 and 10. The mean fork length by brood year, sex, and freshwater.ocean rearing ages for spring chinook returning to the Wind River spawning grounds is currently unavailable.

Sex Ratio

Female spring chinook comprised 56 - 69 percent of the spring chinook returning to the Carson Hatchery between 1979 - 1984 brood years. The percent females by brood year and freshwater.ocean rearing ages for Carson Hatchery returns are presented in Table 9. The percent females by brood year and **freshwater.ocean** rearing ages of the Wind River natural spawners is currently unavailable.

Fecundity

From 1968 - 1984, the number of eggs per female at Carson Hatchery ranged from 3,640 (1968) to 5,180 (1978) and averaged 4,300 (Howell et al., 1985). Wind River natural spawn and Carson Hatchery fecundity data by age and brood year is unavailable.

JUVENILE LIFE HISTORY

Time of Emergence

No information is available on emergence on naturally produced fry. At Carson Hatchery, artificial emergence of nearly "buttoned-up" fry occurs primarily in early January to February after exposure to about 1,750 temperature units (Howell et al., 1985).

Time, age and size at migration

Smolt migration to the Columbia estuary is rapid. Coded wire tagged yearlings released on May 3, 1979 from the Carson Hatchery had a median date of recovery in the estuary (Columbia River Mile 47) on May 12 and May 19, 1979 for beach and purse seine samples, respectively. The final recoveries occurred on May 20, 1979 (**Dawley et al., 1982**).

Hatchery release information for the Wind River **subbasin** by brood year is presented in Table 11. Length data of natural spring chinook smolts from the Wind River is unavailable. The number of natural juvenile spring chinook salmon that migrate from the Wind River is also unavailable.

Survival Rate

Hatchery egg-to-smolt survival is now about 90 percent. Previous problems with Bacterial Kidney Disease reduced fry-to-smolt survival to 65 percent. In recent years, returning adults have been injected with erythromycin and the disease appears to be under control. Smolt-to-adult survival for Carson Hatchery spring chinook has averaged 0.3 percent (**WDW, 1990**). Survival rate has been low (< 0.1 percent) for coded wire tagged yearlings from Carson Hatchery (Howell et al., 1985).

BIOCHEMICAL-GENETIC CHARACTERISTICS

Schreck et. al. (1986) compared the electrophoretic profile from their analysis to the historical baseline data in Milner et al. (1983) in order to evaluate the genetic stability of the isozyme gene frequencies over time. Based on Carson Hatchery samples, isozyme gene frequencies were statistically different for three enzyme systems. The profiles of one of the dissimilar enzymes are normally difficult to interpret and may not reflect actual genetic differentiation.

DISEASE

In 1987, infectious hematopoietic necrosis (**IHN**) was detected in 70 percent of the returning adults; managers used only eggs from non-infected adults. A sample of adults tested positive for IHN in 1988, but the eggs were disinfected with iodophor and retained. The hatchery has subsequently not reported any unusual losses (**WDW, 1990**).

Bacteria and parasitic diseases found in the Carson Hatchery are listed in Table 12.

Table 1 (HB-1). Estimated amount of rearing and spawning habitat, by quality, of the Wind River spring chinook production area;

Distance/Area	Excellent	Good	Fair ^a	Poor ^b	Unknown	Total	Confidence
Miles (%)	00	22	14	64		30	
Acres (%)	00	27	14	59		135.3	

^a Ratings of fair and poor habitat quality may reflect natural physical features such as waterfall barriers, as well as degradation caused by humans.

Age composition prior to 1986 return year is possibly a product of extrapolation using the hatchery age composition. Age composition since 1986 brood is from analysis of scales taken during sport fishery sampling.

No sport fishery occurred from 1980 through 1985.

WIND -RIVER SUBBASIN

Fall Chinook

GEOGRAPHIC LOCATION

The Wind River is located in southwestern Washington and enters the Columbia River above Bonneville Dam at River Mile (RM) 154.5. The Wind is about 30.5 miles long, drains about 225 square miles and lies within Skamania County. Much of the **subbasin** is within the Gifford Pinchot National Forest. Carson National Fish Hatchery is located at Tyee Springs.

ORIGIN

Historically, Bryant (1949) noted a small run of fall chinook below Shipperd Falls. Shipperd Falls at RM 2 is a series of falls approximately 40 feet high that blocked fall chinook migration. Fall chinook in the Columbia are managed as a large aggregate stock and the Wind River stock is part of the Bonneville Pool Hatchery (BPH) "tule" stock (WDW, 1990).

The State of Washington established a salmon hatchery near the mouth of the Wind River in 1899. In 1926, the U.S. Fish and Wildlife Service took over operation for two years, rebuilt the hatchery and gave back operations to Washington Fisheries until the area was inundated in 1938 by the completion of Bonneville Dam (WDF, 1951). The hatchery was solely for the purpose of production of fall chinook stock taken from the Wind River. In 1937, Carson National Fish Hatchery was constructed at Tyee Springs on the Wind River. In the 1940's and early 1950's, operation of the racks at the mouth of the Wind River provided means for counting spawning escapement and egg collection (WDF, 1951). When the Carson Hatchery was built its production was primarily fall chinook. Over time the emphasis has switched to the production of spring chinook with no hatchery production of fall chinook. The last known hatchery release of fall chinook in the Wind River was in 1976.

DISTRIBUTION

In 1956, Shipperd Falls were **laddered** permitting salmon access to the upper areas. Fall chinook have been observed up to Carson Hatchery but the majority of spawning occurs in the lower river.

PRODUCTION

No fall chinook hatchery production has occurred in the Wind River in recent years, and natural production is the dominant component in the Wind River. These fall chinook are managed with the aggregate BPH "tule" stock. Both "tule" and "bright" stocks are present in the Wind River.

Tables 1 and 2 describe the amount of spawning and rearing habitat by quality, available in the Wind River. This data was derived from the Presence/Absence database of Northwest Power Planning Council, 1991.

Carrying capacity was estimated at 206,608 smolts, based on the Northwest Power Planning Council's model. Production of fall chinook may be limited by low water flows.

The Wind River fall chinook natural spawn escapement from 1986 - 1990 averaged 502 adults with a low of 11 for 1990 and a high of 1,206 in 1988. Wind River natural escapement by age and brood year for tule fall chinook are presented in Table 4. Total returns of bright fall chinook to the Wind River by age and brood year is presented in Table 3.

Wind River tributary sport catch estimates for tule fall chinook between 1984 - 1986 brood years

averaged 1 adult **fall** chinook, ranging from a low of zero in 1986 to a high of 2 in 1984, based on punch card data. Wind River tributary sport catches by age and brood year is listed in Table 2.

ADULT LIFE HISTORY

Run size, catch and escapement

Life history data is unavailable for the Wind River fall chinook but is assumed to be similar to Spring Creek Hatchery fish. Ocean commercial and recreational fisheries from Alaska to Washington, in addition to Columbia River gill net and sport fisheries, all harvest a portion of the Wind River origin fall chinook.

From 1970 through 1979, the BPH fall chinook run averaged about 104,000 adults (Howell et al. 1985). In 1980 - 1984, natural and hatchery escapements were adjusted, based on coded-wire tag recoveries, for chinook straying to non-origin areas.

Strays from other hatcheries are common. Strays of bright and tule fall chinook are presented in Tables 5 and 6, respectively.

Time of Migration

BPH fall chinook enter the Columbia in August and migrate until October. BPH stock counts peak at Bonneville Dam around September 4, and September 9 (Howell et al. 1985). About 90 percent of the run has migrated past Bonneville Dam by September 20 (Howell et al. 1985).

Spawning Period

Natural spawning occurs in the Wind River in late September and October.

Spawning Areas

Fish have been observed up to the Carson Hatchery but most spawning occurs in the lower two miles below Shipperd Falls.

Age Compoosition

Assuming similarities with Spring Creek stock, BPH fall chinook mature primarily as three-year-old adults (Howell et al. 1985). Ages also range from two-year-old jacks to five-year-old adults. Age composition percent by brood year for fall chinook spawning naturally is presented in Table 7.

The mean 'fork length by brood year and age class (freshwater-ocean) for female and male tule fall chinook spawning naturally are presented in Tables 9 and 10, respectively.

Sex Ratio

Female fall chinook comprised 48-100 percent of the fall chinook returning to the Wind River for the 1978 - 1984 brood years. The percent females by brood year and freshwater.ocean rearing ages for the Wind River natural spawners are presented in Table 8.

Fecundity

Fecundity averaged 4,700 eggs per female in the Wind River, based on similarities with Spring Creek Hatchery stock. Specific percent fecundity of natural spawning fall chinook by age and brood year is unavailable.

JUVENILE LIFE HISTORY

Time of Emergence

Fry emerge in January through March (WDW, 1990).

Time, age and size at migration

As **fingerlings, fall** chinook emigrate from the Wind River **subbasin** in spring and early summer. Length data of natural **fall** chinook smolts is unavailable. The number of natural fall chinook salmon that migrate from the Wind River is unavailable.

Hatchery release information for the Wind River by brood year is presented in Table 11.

Survival Rate

A general survival rate of 2.0 percent may be appropriate based on the survival rate of Spring Creek juvenile study by TAC (1984).

DISEASE

Data not available.

BIOCHEMICAL-GENETIC CHARACTERISTICS

Data not available.

Table 1 (HB). Estimated amount of rearing and spawning habitat, by quality, of the Wind River fall chinook production area.

Distance/Area	Excellent	Good	Fair ^a	Poor	Unknown.	Total	Confidence
Miles (%)	100	0	0	0		3.9	
Acres (%)	100	0	0	0		28.4	

^a Ratings of fair and poor habitat quality may reflect natural physical features such as waterfall barriers, as well as degradation caused by humans.

Source: Presence/Absence database, NPPC, 1991.

WIND SUBBASIN

Coho

GEOGRAPHIC LOCATION

The Wind River is located in southwestern Washington and enters the Columbia above Bonneville Dam at River Mile **(RM)** 154.5. The Wind River is about 30.5 miles long, drains about 225 square miles and lies within Skamania County. Much of the **subbasin** is within the Gifford Pinchot National Forest. Carson National Fish Hatchery is located at Tyee Springs (RM 18).

An Indian “in-lieu” fishing site has been set aside near the Wind River mouth in compensation for tribal fishing grounds inundated by Bonneville Dam.

ORIGIN

Limited surveys indicate no evidence of natural spawning **coho** in the Wind River.

For 1973 through 1984, at least 75 percent of the **coho** migrating past Bonneville Dam can be accounted for in catches and at hatchery facilities. The remaining escapement of approximately 11,000 adults probably entered tributaries between Bonneville and **McNary** Dams. On the Washington side of the Columbia River these tributaries include the Wind, Little White Salmon, Klickitat, and Yakima Rivers **(WDW, 1990)**.

Biological data for the Wind River **subbasin** is assumed to be similar to **coho** returning to the Little White Salmon National Fish Hatchery.

DISTRIBUTION

Very limited surveys and electroshocker sampling by Washington Department of Fisheries indicate no evidence of **coho** above Shipperd Falls.

PRODUCTION

No significant **coho** hatchery production currently exists at the Carson Hatchery and none is anticipated **(WDW, 1990)**. Potential was identified for early and late returning **coho** in surveys for the Columbia River Fisheries Development Program. In 1944 and 1973, the Carson Hatchery did raise **coho** for release in the Wind River. Other hatchery releases have **also** occurred in the Wind River. Table 2 shows hatchery releases by brood year into the Wind River.

The Northwest Power Planning Council’s carrying capacity model estimated that 146,380 smolts could be produced **(WDW, 1990)**.

Table 1 describes the amount of spawning and rearing habitat, by quality, available in the Wind River. This data was derived from the Presence/Absence database of the Northwest Power Planning Council, 1991.

Wind River tributary sport catch estimates between 1977 - 1988 return years averaged 17 adult **coho**, with none caught for the 1982 - 1985 return years and a peak of 103 in 1986 **(WDW, 1990)**. However, specific age and brood year analysis for Wind River sport catch is unavailable.

ADULT LIFE HISTORY

Run size, catch and escapement

Ocean commercial and recreational fisheries off the Oregon coast are the primary harvesters of early **coho**. The Oregon troll fishery accounts for the highest percentage of the overall catch. Most of the freshwater recreational harvest occurs in the Washington tributaries (Howell et al. 1985).

Based on coded-wire tagged releases of 1976 - 1978 brood late **coho**, most of the harvest occurs in the Washington and Oregon ocean fisheries. Late **coho** have a more northerly migration pattern than early **coho** (WDF, 1990). This is reflected in the catch distribution where the Washington coastal catch comprised 40 percent of the total harvest compared to 20 percent for early **coho** during 1979 - 1981. Late **coho** also contribute significantly to the lower Columbia River commercial gill net fishery (Howell et al. 1985).

Harvest rates have averaged 79 percent and 85 percent for Type-S and N stocks, respectively, between 1983 and 1987. Harvest of Type-S **coho** is occasionally constrained by one or more of the fall chinook stocks. Harvest of Type-N **coho** is generally not constrained by weak stocks, with hatchery escapement being the only management constraint (WDF, 1990).

Time of Migration

Migration is assumed to be similar to that of the **coho** from the Little White Salmon River, which return from September through the first week of November (WDW, 1990).

Spawning Period

Assuming biological similarity to that of the Little White Salmon stock **coho**, spawning occurs in late November.

Spawning Areas

Natural spawning occurs in most areas accessible to **coho**.

Age composition

Assuming biological similarities between the Wind River **coho** and the Little White Salmon **coho**, an average of 10.8 percent return as two-year-old jacks and 89.2 (WDW, 1990) percent of these **coho** return as three-year-old adults. Specific age composition percentages by brood year for **coho** spawning naturally are unavailable.

Sex Ratio

All one-year-old ocean fish were males and 38 percent of two-year-olds were female (WDW, 1990).

Accounting for the differential harvest of adult males and females in the gill net fishery, the adult run entering the Columbia River was estimated to be 46 percent females in 1982 and 30 percent females in 1983. Hatchery adult returns were 33 percent females in 1982 and 34 percent females in 1983 (Howell et al. 1985). Specific percent females by brood year and age class for **coho** spawning naturally are unavailable.

Fecundity

Assuming natural spawning occurs and assuming the Wind River **coho** are similar to the **coho** stock returning to the Little White Salmon River, the Wind River natural spawn fecundity averaged 2,100 eggs per female (**WDW**, 1990). Wind River natural spawn fecundity by freshwater.ocean rearing and brood year is unavailable.

JUVENILE LIFE HISTORY

Time of Emergence

The juvenile life history for Wind **subbasin coho** is similar to that of other stocks in the region with an early spring emergence in mid-January to February (**WDW**, 1990).

Time, age and size at migration

Based on coded-wire tag recovery studies by Dawley et al. (**1982**), arrival in the Columbia River estuary occurs soon after hatchery release (Howell et al. 1985). Length data of natural **coho smolts** from the Wind River is unavailable. The number of natural juvenile **coho** salmon that migrate from the Wind River is also unavailable.

Survival Rate

A generalized recent year smolt to adult survival rate for **coho** was estimated to be 2.5 percent (**TAC** 1983, Howell et al. 1985).

BIOCHEMICAL-GENETIC CHARACTERISTICS

Data has not been compiled.

DISEASE

Data has not been compiled.

WIND RIVER SUBBASIN

Naturally -Produced Summer Steelhead

GEOGRAPHIC LOCATION

The Wind River is located in southwest Washington and flows approximately 30.5 miles before entering the Columbia River above Bonneville Dam at river mile (RM) 154.5. The Wind flows through varying terrain starting with the steep narrow canyons which surround the headwaters, to the wide floodplain which is characteristic of the mid-river ending with the lower 10 miles of river plunging through a series of steep, rapidly descending chutes. The watershed drains approximately 225 square miles mostly within the Gifford Pinchot National Forest.

ORIGIN

The wild summer steelhead stock in the Wind River is native, although interbreeding with introduced Skamania hatchery stock has likely occurred.

DISTRIBUTION

Summer steelhead are distributed throughout the **mainstem** Wind River and within most tributaries including the Little Wind River (RM 1.1), Panther Creek (RM 4.3), Bear Creek (RM 4.3), Trout Creek (RM 10.8), Trapper Creek (RM 18.9), Dry Creek (19.1), and Paradise Creek (RM 25.1). High drop-offs and waterfalls are in some of these streams, some have been modified to permit fish passage while others continue to prevent or impede fish passage. **Shipherd Falls**, located on the **mainstem** Wind river at RM 2.1, consisted of a series of cascading falls approximately 40 feet high and although access over the falls was difficult, steelhead were known to negotiate the stair-step falls under favorable conditions. In 1956, **Shipherd Falls** was **laddered** allowing all anadromous fish access to the upper basin.

PRODUCTION

Production Facilities

One hatchery operates in the subbasin, Carson National Fish Hatchery under the direction of the U.S. Fish and Wildlife Service. Carson Hatchery rears and releases spring chinook into the Wind River. No hatchery steelhead production occurs within the Wind River basin.

Production Summary

No data are available on smolt production. Smolt capacity for summer steelhead was estimated at 62,273 fish based on Northwest Power Planning Council smolt production model (1990). The Washington Department of Wildlife developed a methodology for estimating smolt production based on stream gradient and known densities of parr in Washington streams. Using this method Lucas and Nawa (1986) calculated 23,498 smolts could be produced in the subbasin.

Production constraints are primarily from logging in the upper watershed which has resulted in increased sediment deposits, destruction of riparian habitat, log or debris jams and high summer water temperatures. In addition, construction of Bonneville Dam inundated the lower one mile of river destroying spawning and rearing habitat.

ADULT LIFE HISTORY

Run Size and Escapement

Limited data on run size and escapement. Escapement from- 1985 through 1991 averaged 478 fish (Tables 2 and 3). Historically, the Wind River was renowned for a large run of summer steelhead, which according to estimates obtained from angler surveys, numbered 2,500 to 5,000 fish prior to 1950 (Howell et al. 1985). In addition, reports stated that large numbers of steelhead were seen congregating below **Shipherd** Falls in June waiting to migrate into the upper river.

Time of migration

Adult time of entry for summer steelhead into the Wind River is generally from March through December with peak returns occurring between July and October.

Harvest

Ocean catch of Wind River steelhead is unknown. Harvest of returning adult summer steelhead within the Columbia River is estimated at 7.7 percent above Bonneville Dam and 2.4 percent below Bonneville Dam based on the System Planning Model.

Since 1982, Wind River sport fishing regulations require release of all wild steelhead caught between June 1 and November 30. Since 1990, the Wind River has had wild fish release regulations year round and only adipose-clipped hatchery fish may be retained. In addition, restrictions on access to fish **Shipherd** Falls were implemented to protect wild returning summer steelhead which tend to congregate in these areas. To protect juveniles, a 12 inch minimum size and two fish bag limit for trout was also imposed. Harvest of Wind River steelhead averaged 1,373 fish from 1977 through 1982 but declined to 421 fish from 1983 through 1991 after wild release regulations were imposed and plants halted for a couple of years. Harvest also remained low during the mid 1980's due to cancellation of hatchery smolt releases into the river. Harvest has increased in recent years as hatchery releases resumed in 1986 (Table 2).

The Wind River **subbasin** is part of Yakima Indian Nation lands and thus entitles the tribe to legally catch an equal portion of the harvestable fishery resources.

Spawning period

Spawning usually occurs from February through May with March through April being the peak time.

Spawning areas

Spawning occurs in the **mainstem** Wind River and its major tributaries.

Fecundity

No data are available for the Wind River.

Age Comnosition

Limited data on adult age structure. Based on 19 wild fish collected in 1981, 58 percent were 2.2

age class and 26 percent were 2.3 age **class** (Table 4).

Size

Mean fork lengths from wild summer steelhead caught in 1981 ranged from 65 cm to 84 cm. Table 6 presents lengths for individual age classes.

Sex ratio

Sex ratio for 19 wild steelhead caught in 1981 was 63 percent female (Table 5).

Survival Rate

No data are available on Wind River steelhead.

JUVENILE LIFE HISTORY

Egg

No data on egg production or egg to smolt survival.

Emergence

Emergence occurs from May through June.

Juvenile rearing

Juvenile rearing lasts approximately two years prior to ocean emigration, although some juveniles emigrate after one or three years (Loch et al. 1985). Juvenile migration generally occurs from April through May with peak migration in early May.

Hatchery Releases

Skamania hatchery stock is the exclusive hatchery stock planted in the Wind River. Data relating to Skamania stock returning to the Wind River is unknown. However, Leider has intensively studied and recorded information on the Skamania stock on the Kalama River and that information is presented in the Kalama River summer steelhead report. Table 7 listed hatchery releases into the Wind River from 1981 through 1990.

BIOCHEMICAL-GENETIC CHARACTERISTICS

No direct data on Wind River stocks, although Schreck (1986) studied stock identification of various Columbia River steelhead, including Wind River stock, using cluster analysis of meristic and electrophoretic characteristics and determined that geographical proximal stocks tend to be like each other.

DISEASES

Disease history for smolts planted in the Wind River is presented in Table 8.

WIND RIVER SUBBASIN

Naturally Produced Winter Steelhead

GEOGRAPHIC LOCATION

The Wind River is located in southwest Washington and flows approximately 30.5 miles before entering the Columbia River above Bonneville Dam at river mile (RM) 154.5. The Wind flows through varying terrain starting with the steep narrow canyons which surround the headwaters, to the wide floodplain which is characteristic of the mid-river ending with the lower 10 miles of river plunging through a series of steep, rapidly descending chutes. The watershed drains approximately 225 square miles mostly within the Gifford Pinchot National Forest.

ORIGIN

The wild winter steelhead stock in the Wind River is native, although interbreeding with introduced Chambers Creek hatchery stock during the 1950's may have occurred.

DISTRIBUTION

Wind River winter steelhead are distributed throughout the **mainstem** Wind River with fish distributed above **Shpherd** Falls up to Trout Creek (Howell et al. 1985) and probably throughout the system.

PRODUCTION

Production Facilities

One hatchery operates in the subbasin, Carson National Fish Hatchery under the direction of the U.S. Fish and Wildlife Service. Carson Hatchery rears and releases spring chinook into the Wind River. No steelhead production occurs within the Wind River basin.

Production Summary

No data are available on smolt production. Smolt capacity for winter steelhead was estimated at 3,764 fish based on Northwest Power Planning Council (1990) smolt production model. Production constraints are primarily from logging in the upper watershed which has resulted in increased sediment deposits, destruction of riparian habitat, log or debris jams and high summer water temperatures. In addition, construction of Bonneville Dam inundated the lower one mile of river destroying spawning and rearing habitat.

ADULT LIFE HISTORY

Run Size and Escapement

No data on run size and escapement. Currently, the wild winter steelhead run size is considered **small** at an estimated 60 fish (Howell et al. 1985). Historically, the winter steelhead run size was thought to be small with summer steelhead comprising the vast majority of steelhead returns. No life history information exists for this stock.

Time of migration

Adult time of entry for winter steelhead into the Wind River is probably from January through May with peak returns occurring in March.

Harvest

Ocean catch of Wind River steelhead are unknown.

Harvest of returning adult winter **steelhead** within the Columbia River is unknown, However, the Columbia River treaty Indian and sport fishery catches large numbers of steelhead with some Wind River steelhead likely being part of the Columbia River harvest. The sport fishery also results in the harvest of an unknown (but presumed smaller) number of steelhead.

Wind River sport fishing regulations require release of all wild steelhead, only adipose-clipped hatchery fish may be retained. In addition, restrictions on access to **fish Shipherd** Falls were implemented to protect wild returning steelhead which tend to congregate in these areas. To protect juveniles, a 12 inch minimum size and two fish bag limit for trout was also imposed. Sport catch of winter fish is unknown, although using a December through May catch period, as reported on angler permit cards, winter catch averaged 84 fish from 1977 through 1988.

The Wind River **subbasin** is part of the Yakima Indian Nations lands and thus entitles the tribe to legally catch a equal portion of the harvestable fishery resources.

Spawning period

Spawning is primarily from March through June.

Spawning area

Winter steelhead have been documented spawning as far upstream as Trout Creek.

Fecundity

No data are available for Wind River steelhead.

Age Comnosition

No data are available for Wind River steelhead.

Size

No data are available for Wind River steelhead.

Sex ratio

No data are available for Wind River steelhead.

Survival Rate

No data are available for Wind River Steelhead.

JUVENILE LIFE HISTORY

Egg

No data on egg production or egg to smolt survival.

Emergence

Emergence data unknown.

Juvenile rearing

Juvenile rearing lasts approximately two years prior to ocean emigration.

Juvenile migration generally occurs from April through May with peak migration in early May.

Hatchery Releases

Currently, no hatchery produced winter steelhead are planted in the Wind basin, Hatchery releases of Chambers Creek stock were conducted in the 1950's and early 1960's. Adult returns from these releases were poor and hatchery releases were discontinued.

Straying

No data are available on Wind River steelhead.

BIOCHEMICAL-GENETIC CHARACTERISTICS

No data are available on Wind River steelhead.

DISEASES

No data are available on Wind River steelhead.

WHITE SALMON SECTION CONTENTS

The White Salmon River chapter is composed of three sections: the White Salmon (sometimes called the Big White Salmon), the Little White Salmon, and the **Spring Creek** National Fish Hatchery.

The Little White Salmon River enters the Columbia about six miles below the mouth of the Big White Salmon River. Reporting for the Little White Salmon River follows after the Big White Salmon section.

The Spring Creek National Fish Hatchery is located on the Columbia River, about a mile below the mouth of the Big White Salmon River. Reporting for this facility follows that of the Little White Salmon.

WHITE SALMON SUBBASIN

Spring Chinook

GEOGRAPHIC LOCATION

The White Salmon (also commonly called the Big White Salmon) River is located in south central Washington in **Klickitat** and **Skamania** counties. The river begins on the southwest slope of Mount Adams and flows south about 45 miles into Bonneville Pool on the Columbia River (**RM 168.3**). Drainage area is approximately 386 square miles. Approximately 47 percent of the **subbasin** is in the Gifford Pinchot National Forest. The White Salmon rearing ponds are located at **RM 1.5**.

The U. S. Army Corps of Engineers has established an "in-lieu" site for tribal fishing access at the mouth of the river. The site has been set aside in compensation for tribal fishing grounds inundated by the Bonneville Dam reservoir.

ORIGIN

Spring chinook were formerly present in the **subbasin** and Indians fished for salmon (probably spring chinook) at the falls near Husum (**Fulton 1968**). However, with exception of returns from recent hatchery fingerling plants above Condit, spring chinook are not present in the **subbasin**. Cowlitz (**1982**), Little White Salmon (1986) and Carson (1984-86, and 1988 and 1990) stocks have been released into the White Salmon River **subbasin** (**WDW, 1990**).

DISTRIBUTION

Historical distribution was probably confined below the falls at **RM 16.3**. Condit Dam has blocked all migration past **RM 3.3** since 1917. Two attempts to ladder the dam failed.

PRODUCTION

Between 1982 through 1986, hatchery juvenile spring chinook have been periodically released into the upper **mainstem** and Trout Lake Creek above **RM 16.3**. The White Salmon rearing ponds released juvenile spring chinook in 1988 and 1990.

The White Salmon rearing ponds, located at **RM 1.5**, were originally constructed to as adult brood stock facilities. The ponds were used for rearing fall chinook until 1984. The ponds are susceptible to flooding and in January 1990 about 1 million fry were released **early** during high water. Disposition of the ponds for rearing is presently uncertain. Rearing capacity of the facility could be expanded to accommodate 1,450,000 smolts, which is recognized as a long-term program need in United States vs. Oregon. The U.S. Fish and Wildlife Service owns 40 acres of land at the site, however funds are not presently available for hatchery expansion (**WDW, 1990**).

The Northwest Planning Council's habitat capacity model indicated 297,437 smolts could be produced above Condit Dam, including 113,685 between Condit Dam and the falls at **RM 16.3**. Young and Rybak (1987) estimated 35,000 smolts could be produced above Condit. Chapman (1981) estimated the White Salmon could produce 625 adult chinook (springs and falls) under pristine conditions.

In 1988 and 1989, the Washington Department of Fisheries recorded a peak spawning count of 73 and 40 adult fish, respectively, below Condit Dam. White Salmon River spring chinook natural spawn escapement by age and brood year is unavailable. White Salmon River spring chinook sport catch estimates has been near zero from 1977 through 1986 but 51 adults were caught in 1987 (**WDW, 1990**). White Salmon River sport catches by age and brood year is unavailable.

ADULT LIFE HISTORY

Run size, catch and escapement

Ocean commercial and recreational fisheries from Alaska to Washington, in addition to Columbia River gill net and sport fisheries all harvest a portion of the **White** Salmon River origin spring chinook. Out-of-basin harvest on Bonneville Pool stocks, which includes ocean and Columbia River harvest, has averaged about 15 percent (**WDW**, 1990). Columbia River sport and commercial fisheries are managed to minimize harvest of depressed upriver stocks.

Strays from other hatcheries are uncommon. Table 1 lists the coded wire tags from the 1978 brood through the 1988 brood recovered within the White Salmon **subbasin** which originated outside the White Salmon subbasin. White Salmon River spring chinook releases have been generally untagged.

Time of Migration

Spring chinook destined for areas upstream of Bonneville Dam begin entering the Columbia River in large numbers in mid-March. Counts peak at Bonneville Dam usually between April 20 and April 28 but can be earlier during abnormally low flow years or later during high run-off. Adult spring chinook enter the **subbasin** from April to July.

Spawning Period

Natural spawning occurs during the latter part of August and early September.

Spawning Areas

Natural spawning occurs in the three mile stretch downstream from Condit Dam.

Age Composition

White Salmon River data are unavailable. However, Carson stock typically ranges from **three-year-old** jacks to six-year-old adults with four-year-olds or five-year-olds the dominant age classes. Carson stock has been the recent egg source for White Salmon releases.

Sex Ratio

White Salmon River data are unavailable. However in adjacent Carson Hatchery, females comprised 56 - 69 percent of the spring chinook returning to the Carson Hatchery between 1979 - 1984 brood years.

Fecundity

Fecundity data are not available for White Salmon spring chinook. From 1968 - 1984, the number of eggs per female at Carson Hatchery ranged from 3,640 (1968) to 5,180 (1978) and averaged 4,300 (Howell et al. 1985).

JUVENILE LIFE HISTORY

Time of Emergence

No information is available on the naturally produced population. At Carson and Little White Salmon hatcheries, artificial emergence of nearly "buttoned-up" fry occurs primarily in early January to February after exposure to about 1,750 temperature units (**Howell** et al. 1985).

Time, age and size at migration

Hatchery release information for the White Salmon **subbasin** by brood year is presented in Table 2. Length data of natural spring chinook smolts from the White Salmon River is unavailable. The number of natural juvenile spring chinook salmon that migrate from the White Salmon River is also unavailable.

Survival Rate

White Salmon River survival rate is not available. Smolt-to-adult survival for Carson Hatchery spring chinook has averaged 0.3 percent (WDW, 1990).

BIOCHEMICAL-GENETIC CHARACTERISTICS

No data available.

DISEASE

Bacteria and parasitic diseases found in the White Salmon River are unavailable.

WHITE SALMON SUBBASIN

Fall Chinook

GEOGRAPHIC LOCATION

The White Salmon (also commonly called the Big White Salmon River) is located in south central Washington in Klickitat and Skamania counties. The river begins on the southwest slope of Mount Adams and flows south about 45 miles into Bonneville Pool on the Columbia River (RM 168.3). Drainage area is approximately 386 square miles. Approximately 47 percent of the subbasin is in the Gifford Pinchot National Forest. The White Salmon rearing ponds are located at RM 1.5.

The U. S. Army Corps of Engineers has established an "in-lieu" site for tribal fishing access at the mouth of the river. The site has been set aside in compensation for tribal fishing grounds inundated by the Bonneville Dam reservoir.

ORIGIN

Fall chinook are native to the White Salmon River and some natural production presently occurs below Condit Dam.

In addition to the historically abundant tule fall chinook, the White Salmon River has supported a substantial population of upriver bright fall chinook in recent years. Significant numbers of fall chinook spawning occurred in the White Salmon during October and November in 1987 and 1988. Coded wire tag recoveries from carcasses sampled during late fall 1987 and 1988 revealed those fish were primarily stray Upriver Bright stock from Bonneville and Little White Salmon Hatcheries. Over 59 percent of the late natural spawning fall chinook in the White Salmon River in 1989 were estimated to be of hatchery origin, primarily Little White Salmon Hatchery upriver brights (Hymer, 1991).

DISTRIBUTION

Historical distribution was probably confined below the falls at RM 16.3. Condit Dam was built in 1913 at RM 3 and blocked upstream migration of anadromous fish. Two attempts to ladder the dam failed.

PRODUCTION

Bonneville Pool Hatchery (BPH) "tule" brood stock was originally taken from the White Salmon River and other nearby rivers. In 1901, fall chinook eggs collected from the White Salmon River were transferred to facilities on Spring Creek. In 1986 and 1987, tule fall chinook returns were trapped at the White Salmon weir and the eggs transferred to Spring Creek National Fish Hatchery for incubation and rearing. No fall chinook have been trapped at the White Salmon weir since 1987.

Rearing ponds on the White Salmon River at RM 1.5 were used to rear fall chinook fingerlings through 1984. Fish were reared from early March until a May release. However, poor adult returns resulted in discontinuation of the program.

Table 1 describes the amount of spawning and rearing habitat, by quality, available in the White Salmon River.

The Northwest Power Planning Councils smolt capacity model estimated 127,426 fall chinook fingerlings could be produced below Condit Dam. However, production may be limited by gravel

quantity. Potential production between Condit Dam and RM 16.3 was estimated to be 32,000 smolts by Young and Rybak (1987). Evidence suggests bright fall chinook natural production may be occurring (Hymer, 1991). Chapman (1981) estimated the White Salmon could produce 625 natural chinook (springs and falls) under pristine conditions.

The White Salmon tule fall chinook natural spawn escapement from 1980 - 1984 brood years averaged 267 with a low return of 135 in 1983 and a peak of 439 in 1984. The White Salmon tule chinook natural spawn escapements by age and brood year are presented in Table 2.

The White Salmon River upriver bright fall chinook natural escapement for 1989 and 1990 return years was 2,997 and 1,182 fish, respectively (Hymer, 1991). The White Salmon upriver bright fall chinook natural spawn escapements by age and brood year are presented in Table 3. There were no upriver bright fall chinook stream surveys on the White Salmon River before 1987; therefore, brood year return information is incomplete.

From 1977 through 1987, an average of 48 fish were sport caught in the **subbasin** (WDW, 1990). However, stock specific age and brood year analysis for the White Salmon River sport catch is unavailable.

The tule fall chinook trapped at the White Salmon weir in 1986 and 1987 and upriver brights trapped in 1987 by age and brood year are presented in Tables 4 and 5, respectively.

ADULT LIFE HISTORY

Run size, catch and escapement

Ocean commercial and recreational fisheries from Alaska to Washington, in addition to Columbia River gill net and sport fisheries all harvest a portion of the White Salmon River origin fall chinook. Out-of-basin harvest may approach 80 percent on Bonneville Pool Hatchery stocks with fish contributing to ocean and mainstem Columbia River fisheries (WDW, 1990). Based primarily on Spring Creek Hatchery 1971 and 1972 brood coded wire tag releases, about 38 percent of the overall BPH harvest occurred off the Washington coast and 20 percent in the Columbia River commercial fisheries. Recreational catch upstream of the Megler-Astoria Bridge is negligible (Howell et al. 1985). From 1977 through 1987, the White Salmon River **subbasin** sport harvest rate was 8.5 percent (WDW, 1990). Columbia River sport and commercial fisheries are managed to ensure attainment of hatchery egg-take requirements.

Strays from other hatcheries are not unusual. Tables 6 and 7 list the coded wire tags beginning with the 1978 brood through the 1988 brood recovered within the White Salmon **subbasin** which originated outside the White Salmon **subbasin**. However, federal hatchery origin coded wire tags recovered during spawning ground surveys after 1983 are currently unavailable. White Salmon releases have been generally untagged.

Time of Migration

Tule fall chinook upstream migration occurs in early August and September with greatest abundance in the Columbia River estuary in late August and early September. Counts of BPH fall chinook at Bonneville Dam generally peak between September 4 and September 9. Approximately 90 percent of the run has migrated past Bonneville by September 20 (Howell et al. 1985),

Upriver bright fall chinook migration curve is more prolonged and gradual compared to tule fall chinook passing Bonneville Dam. Upriver bright fall chinook migration occurs through November.

Spawning Period

Tule fall chinook natural spawning peaks in late September to early October while upriver bright fall chinook natural spawning peaks in early to mid November.

Spawning Areas

Spawning occurs in the three mile stretch below Condit Dam.

Age Composition

Age ranges from two-year-old jacks to five-year-old adults with three-year-olds and four-year-olds usually the dominant age classes for tule fall chinook. Total age composition data for both tule and upriver bright fall chinook are summarized in Tables 2 through 5. Table 8 lists the age composition percentages by brood year and **freshwater.ocean** rearing for tule fall chinook returning to the White Salmon River spawning grounds.

Sex Ratio

Female tule fall chinook comprised 47 - 62 percent of the tule fall chinook natural spawners in the White Salmon River for the 1983 and 1984 brood years. The percent females by brood year and **freshwater.ocean** rearing ages for the White Salmon tule fall chinook natural spawners are presented in Table 9.

Percent females by brood year and age class (**freshwater.ocean**) for tule **fall** chinook trapped at the White Salmon weir in 1986 and 1987 are presented in Table 10.

The mean fork length by brood year, sex, and **freshwater.ocean** rearing ages of the White Salmon River tule fall chinook natural spawners for 1980 - 1984 brood years are available in Tables 11 and 12.

The mean fork length by brood year, sex, and **freshwater.ocean** rearing ages of the tule fall chinook trapped at the White Salmon weir in 1986 and 1987 are presented in Tables 13 and 14.

Fecundity

Fecundity data are not available for White Salmon fall chinook. However, Spring Creek Hatchery tule fall chinook fecundity are probably similar. Fecundity averaged 4,700 eggs per female at Spring Creek Hatchery from 1978 - 1982.

Fecundity of upriver bright fall chinook at Bonneville Hatchery is 4,503 eggs per female (Howell et al. 1985)

JUVENILE LIFE HISTORY

Time of Emergence

Emergence probably occurs in February and fish rear for a few months prior to spring or early summer ocean migration (**WDW**, 1990).

Time, age and size at migration

Based on recoveries of tagged tule Spring Creek juveniles, migration to the Columbia River estuary is rapid and generally occurs within 1 - 3 weeks after release (Howell et al. 1985). Length data of

natural fall chinook smolts from the White Salmon River is unavailable. The number of natural juvenile fall chinook salmon that migrate from the White Salmon River is also unavailable. Hatchery release information for the White Salmon **subbasin** by brood year is presented in Table 15.

Survival Rate

BPH fall chinook reared and released from Spring Creek Hatchery are noted for their generally high survival rate. Spring Creek **substock** fall chinook reared at other stations do not experience the same high survival. A minimum survival rate (partial catch and escapement) of four groups of coded wire tagged Spring Creek Hatchery releases ranged between 0 - 1.9 percent (1978 brood) and 0.3 - 2.1 percent (1979). Survival of the 1979 brood releases was based on only two years of catches. These rates were much higher than the average of 0.2 percent for the 1978 and 1979 brood tule releases from other stations (Howell et al. 1985). TAC (1984) estimated a general survival rate of Spring Creek Hatchery releases at 2.0 percent which did not include mortality on juvenile outmigrants caused by Bonneville Dam.

BIOCHEMICAL-GENETIC CHARACTERISTICS

Schreck et al. (1986) compared isozyme gene frequencies for 11 enzyme systems from samples collected at Bonneville and Spring Creek Hatcheries. No statistically significant differences were found for any of the enzymes. They did not, however, analyze fall chinook from the White Salmon basin.

DISEASE

Bacteria and parasitic diseases found in the White Salmon are unavailable.

Table 1 (HB-1). Estimated amount of rearing and spawning habitat, by quality, of the Big White Salmon River fall chinook production area.

Distance/Area	Excellent	Good	Fair ^a	Poor ^a	Unknown	Total	Confidence
Miles (%)	100	0	0	0		3.3	
Acres (%)	100	0	0	0		17.5	

^a Ratings of fair and poor habitat quality may reflect natural physical features such as waterfall barriers, as well as degradation caused by humans.

LITTLE WHITE SALMON

Spring Chinook

GEOGRAPHIC LOCATION

The Little White Salmon River, located in Skamania County in south central Washington, drains approximately 134 square miles. The river originates in the Gifford Pinchot National Forest, west of Monte Cristo Peak, and travels south for about 19 miles before entering Bonneville Pool on the Columbia River at River Mile (RM) 162, about six miles below the confluence of the White Salmon River and the Columbia. A railroad embankment and highway about one-half mile below the original mouth of the river cuts off a shallow embayment from the Columbia River and forms 212 acre Drano Lake. Two federal fish hatcheries are located on the river, the Little White Salmon National Fish Hatchery (NFH) at RM 1 and Willard NFH at RM 5.

ORIGIN

Spring chinook may have been historically present in small numbers below the barrier falls in the lower river (Bryant 1949). However, since Bonneville Pool inundated the lower river, only hatchery fish are present.

Spring chinook releases began in the late 1960's using Eagle Creek NFH stock plus strays returning to the Little White Salmon River. Those strays were probably the returns from off station releases of Willard and Carson Hatcheries. South Santiam (1974 brood) and Klickitat (1968 and 1974 broods) stock spring chinook were also reared and released at Little White Salmon Hatchery. Recently, the Little White Salmon Hatchery began to use it's own returns and/or received eggs from Carson Hatchery. Spring chinook raised at the Little White Salmon Hatchery are considered a Carson stock derivative (Howell et al. 1985).

DISTRIBUTION

Anadromous fish migration is completely blocked by a series of waterfalls approximately 37 feet high located about two miles upstream of the Columbia River. When Bonneville Dam was completed in 1938, this area was inundated and any natural salmon production ceased.

PRODUCTION

Currently, spring chinook in the Little White Salmon River are from hatchery production.

The Northwest Power Planning Councils habitat capacity model indicated that a total of 32,350 spring chinook smolts could be produced using all subbasin habitat. Constraints included the basin size, steep gradients, low summer flows, and lack of spawning habitat.

Little White Salmon Hatchery spring chinook returns from 1967 - 1984 brood years averaged 1,495 with a low return of 239 for the 1970 brood and a high of 5,051 for the 1973 brood. Little White Salmon Hatchery returns by age and brood year are presented in Table 1.

Little White Salmon River tributary sport catches for the 1971, 1973, 1974, and 1978 return years averaged 5 jack spring chinook. Only jacks were allowed in the sport catch prior to 1979. Little White Salmon sport catch estimates for 1979 through 1990 (without 1980 and 1984) return years averaged 682 spring chinook, and ranged from a low of 7 in 1981 to a high of 1,800 in 1988 (based on punchcard and actual sampling data). Little White Salmon River spring chinook sport catches by age class and brood year are presented in Table 2.

Little White Salmon River tribal harvest (including hatchery donations) for 1982 - 1990 (without 1983 and 1984) return years averaged 1,174 spring chinook, and ranged from a low 410 in 1985 to a high of 1,897 in 1987. Surplus spring chinook from the hatchery were donated to the tribes up until 1989. In 1989, a tribal commercial fishery harvested 877 spring chinook from Drano Lake. In 1990, 386 fish were donated to the Yakima Indian Nation and 296 were from a tribal subsistence fishery in Drano Lake. Little White Salmon River spring chinook tribal harvest (including hatchery donations) by age class and brood year are listed in Table 3.

The Little White Salmon River spring chinook total returns from 1967 - 1984 brood years averaged 2,055 with a low of 158 for the 1969 brood and a high of 9,056 for the 1983 brood. Little White Salmon River spring chinook total returns by brood year and age are presented in Table 4.

ADULT LIFE HISTORY

Run size, catch and escapement

Ocean commercial and recreational fisheries from Alaska to Washington, in addition to Columbia River gill net and sport fisheries all harvest a portion of the Little White Salmon River origin spring chinook. When the Little White Salmon Hatchery is expected to achieve its escapement goal, the Washington Department of Fisheries and the Yakima Indian Nation develop a harvest plan for sharing the harvestable surplus between the recreational fishery and the Yakima tribal members. The sport fishery occurs in Drano Lake. When the sport fishery was open for 1977 through 1986, overall **subbasin** harvest was 8.4 percent (WDW, 1990). The Yakima Indian tribal members usually receive hatchery donations but in 1989 had a set net fishery in Drano Lake at the conclusion of the sport fishery. In 1990, a tribal subsistence set net fishery occurred in Drano Lake. Columbia River sport and commercial fisheries are managed to ensure attainment of hatchery egg-take requirements while minimizing other upriver stocks impacts.

Strays from other lower river hatcheries are not unusual. Table 5 lists coded wire tagged Little White Salmon spring chinook that were non-harvest recovered outside of the **subbasin** (beginning with the 1978 brood through to the 1988 brood). Table 6 lists the coded wire tags recovered within the Little White Salmon River **subbasin** which originated outside the Little White Salmon River subbasin.

Time of Migration

Spring chinook destined for areas upstream of Bonneville Dam begin entering the Columbia River in large numbers in mid-March. Counts high at Bonneville Dam usually between April 20 and April 28 but can be earlier during abnormally low flow years or later during high run-offs.

Adult spring chinook return to the hatchery from April to July. At Little White Salmon Hatchery, approximately 50 percent of the escapement has been collected by the end of May (Howell et al. 1985).

Spawning Period

Fish are held from mid-April through August and spawned from mid-July to August. Since 1982, adults have been held indoors and exposed to lights to advance the photoperiod and induce earlier spawning (Nelson and Bodle, 1988).

Spawning Areas

Little White Salmon Hatchery.

Age Composition

Age ranges from three-year-old jacks to six-year-old adults with four-year-olds usually the dominant age class. Spring chinook released as subyearlings occasionally contribute significantly to the returns to the Little White Salmon River. Age composition is summarized in Tables 1 through 4. Table 7 lists the age composition percentages by brood year and age class for spring chinook returning to the Little **White** Salmon Hatchery.

Sex Ratio

Female spring chinook comprised 58 - 75 percent of the spring chinook returning to the Little White Salmon Hatchery between 1981 - 1984 brood years. The percentage of females by brood year and age class for Little White Salmon Hatchery spring chinook returns are presented in Table 8.

The mean fork lengths by brood year, sex and age classes for spring chinook returning to the Little White Salmon NFH for the 1978 - 1987 brood years are presented in Tables 9 and 10.

Fecundity

During 1978 - 1982, spring chinook fecundity at Little White Salmon Hatchery averaged 4,000 eggs per female and ranged from about 3,800 - 4,800. Little White Salmon Hatchery fecundity data by age class and brood year is unavailable.

JUVENILE LIFE HISTORY

Time of Emergence

Incubation runs from mid-July to mid-December and fry emerge from October to December at Little White Salmon Hatchery.

Time, age and size at migration

Hatchery release information for the Little White Salmon River **subbasin** by brood year is presented in Table 11.

Survival Rate

Egg-to-smolt survival has been about 87.9 percent (WDW, 1990).

BIOCHEMICAL-GENETIC CHARACTERISTICS

Schreck et al. (1986) compared the electrophoretic profiles from their analysis to the historical baseline data in Milner et al. (1983) in order to evaluate the genetic stability of the isozyme gene frequencies over time. In the comparison of current versus historical profiles for Little White Salmon spring chinook, there were no instances of statistically different isozyme gene frequencies.

DISEASE

Infectious hematopoietic necrosis (**IHN**) was detected in the adults returning to the Little White Salmon in 1981. Bacteria and parasitic diseases found in the Little White Salmon and Willard Hatcheries are listed in Tables 12 and 13.

All tribal harvest was provided by hatchery donations except:

1988 return year - harvest from **Drano** Lake tribal commercial fishery.

1990 return year - includes Drano Lake tribal subsistence fishery.

Tribal harvest age composition is a combination of scale samples from the Little White Salmon Hatchery and the Drano Lake sport fishery.

LITTLE WHITE SALMON

Fall Chinook

GEOGRAPHIC LOCATION

The Little White Salmon River, located in Skamania County in south central Washington, drains approximately 134 square miles. The river originates in the Gifford Pinchot National Forest, west of Monte Cristo Peak, and travels south for about 19 miles before entering Bonneville Pool on the Columbia River at River Mile (RM) 162, about six miles below the confluence of the White Salmon River and the Columbia. A railroad embankment and highway about one-half mile below the original mouth of the river cuts off a shallow embayment from the Columbia River and forms 212 acre Drano Lake. Two federal hatcheries are located on the river, the Little White Salmon National Fish Hatchery (NFH) at RM 1 and the Willard NFH at RM 5.

ORIGIN

Fall chinook were historically present in small numbers below the barrier falls in the lower river (Bryant 1949). The chinook salmon run consisted of fish known as "tules." However, fish were unable to pass above the barrier falls and when Bonneville Pool flooded the lower river area, natural production ceased in the subbasin. Hatchery production began in 1896 from eggs collected in the river. Over the years, the hatchery has received eggs from other strains of tule fall chinook (WDW, 1990). Nelson and Bodle (1988) indicated that from 1968 to 1983, 51 percent of the fall chinook released in the Little White Salmon River were not indigenous. Low returns, coupled with little contribution to commercial or sport harvest, led managers to discontinue production of this stock.

In 1984, the hatchery received upriver bright fall chinook eggs from Bonneville Hatchery (WDW, 1990). Brood stock for Bonneville Hatchery and other upriver bright production started from upriver-bound fall chinook trapped at Bonneville Dam and is a mixture of fish from several different production areas above Bonneville (Howell et. al., 1985).

DISTRIBUTION

Anadromous fish migration was completely blocked by a series of waterfalls approximately 37 feet high located about two miles upstream of the Columbia River. Before Bonneville Dam was completed, this short reach supported chinook salmon. When Bonneville Dam was completed in 1938, this area was inundated and natural salmon production ceased.

PRODUCTION

Currently, the Little White Salmon NFH produces bright fall chinook. Fingerlings are released at the hatchery to maintain brood stock for John Day Dam mitigation. Additional fingerlings have also been planted into the Yakima River (WDW, 1990). Slightly more than one-half million 1986 brood upriver bright fall chinook fingerlings were reared in net pens and released into Drano Lake.

The Northwest Power Planning Council's smolt capacity model indicated that a total of 73,652 fall chinook fingerlings could be produced using all subbasin habitat.

Little White Salmon NFH tule fall chinook returns from 1979 - 1983 brood years averaged 981 with a low return of 238 for the 1981 brood and a peak of 2,653 for the 1979 brood. There have been no tule fall chinook returns to the Little White Salmon NFH since 1988. Little White Salmon NFH

tule fall chinook returns by age and brood year are presented in Table 1.

Little White Salmon NFH upriver **bright fall** chinook returns from 1982 - 1984 brood years were 2,989 (1982 brood), 2,582 (1983 brood), and 3,214 (1984 brood) fish, respectively. There were no upriver bright fall chinook returns before 1984. Little White Salmon NFH upriver bright fall chinook returns by age and brood year are presented in Table 2.

Little White Salmon tributary fall chinook sport catch estimates between 1985 - 1987 return years averaged 45 fish (WDW, 1990). However, stock specific age and brood year analysis for the Little White Salmon River sport catch is unavailable.

ADULT LIFE HISTORY

Run size, catch and escapement

Ocean commercial and recreational fisheries from Alaska to Washington, in addition to Columbia River gill net and sport fisheries all harvest a portion of the Little White Salmon River origin fall chinook. Harvest rate within the **subbasin** averaged 2.6 percent for 1985 through 1987 (WDW, 1990). Columbia River sport and commercial fisheries are managed to ensure attainment of hatchery egg-take requirements.

Strays from other hatcheries are common. Tule and upriver bright fall chinook tagged and released from the Little White Salmon NFH, and recovered in other subbasins, are presented in Tables 3 and 4 (beginning with the 1978 brood through to the 1988 brood). Little White Salmon tag recoveries from spawning ground surveys after 1983 are currently unavailable. Coded wire tag recoveries from carcasses sampled from the Big White Salmon River during the fall 1987 through 1990 revealed those **fish** were primarily strays from the Little White Salmon NFH (Hymer, 1991).

The tule and upriver bright fall chinook coded wire tags recovered within the Little White Salmon **subbasin** which originated outside the Little White Salmon **subbasin** are presented in Tables 5 and 6, respectively.

Time of Migration

Tule fall chinook upstream migration occurs in early August and September with greatest abundance in the Columbia River estuary in late August and early September. Counts of tule fall chinook at Bonneville Dam generally peak between September 4 and September 9. Approximately 90 percent of the run has migrated past Bonneville Dam by September 20 (Howell et al. 1985).

Bright fall chinook migration curve is more prolonged and gradual compared to tule fall chinook passing Bonneville Dam. Adult bright fall chinook migration continues through November. Adult upriver brights return to the hatchery from mid-September to November.

Spawning Period

Upriver bright adults are held from mid-October to November and spawned in November.

Spawning Areas

Little White Salmon NFH.

Ane Composition

The age composition of Little White Salmon tule fall chinook ranges from two-year-old jacks to five-year-old adults with three-year-olds or four-year-olds usually the dominant age classes. Little White Salmon NFH tule fall chinook age composition data is summarized in Table 1. Table 7 lists the age composition percentages by brood year for tule fall chinook returning to the Little White Salmon NFH.

The age composition of Little White Salmon upriver bright fall chinook ranges from two-year-old jacks to six-year-old adults with four-year-olds or five-year-olds usually the dominant age classes. Little White Salmon upriver bright fall chinook age composition data is summarized in Table 2. Table 8 lists the age composition percentages by brood year for upriver bright fall chinook returning to the Little White Salmon NFH.

Sex Ratio

Female tule fall chinook comprised 51 - 71 percent of the tule fall chinook returning to the Little White Salmon NFH between 1979 - 1983 brood years. The percentage of females by brood year and age class for Little White Salmon NFH tule fall chinook returns are presented in Table 9.

Female upriver bright fall chinook comprised 44 and 59 percent of the upriver bright fall chinook returning to the Little White Salmon NFH for 1983 and 1984 brood years, respectively. The percent females by brood year and freshwater-ocean rearing ages for Little White Salmon NFH upriver bright fall chinook returns are presented in Table 10.

The mean fork length by brood year, sex, and age class for tule fall chinook returning to the Little White Salmon NFH are presented in Tables 11 and 12.

The mean fork length by brood year, sex, and age class for upriver bright fall chinook returning to the Little White Salmon NFH are presented in Tables 13 and 14.

Fecundity

Fecundity for Little White Salmon River upriver bright fall chinook averaged 4,618 during 1987 - 1990 (USFWS, unpublished).

JUVENILE LIFE HISTORY

Time of Emergence

Incubation usually occurs from November to February and fry emerge in March.

Time, age and size at migration

Currently, the Little White Salmon River fall chinook are from hatchery production. Hatchery release information for the Little White Salmon River **subbasin** by brood year is presented in Table 15.

Survival Rate

Data unavailable.

BIOCHEMICAL-GENETIC CHARACTERISTICS

The upriver bright stock at Bonneville Hatchery (a brood stock source for Little White Salmon upriver brights) originated from upriver bound fall chinook trapped at Bonneville Dam. Since 1981 adult returns to the Bonneville Hatchery and additional fish trapped at the dam have been used as brood stock. These fish may be from several different production areas above Bonneville. Consequently, the genetic characteristics of this stock may be quite mixed (Howell et al. 1985).

DISEASE

IHN was detected in adults in 1981 and common bacterial diseases are bacterial kidney disease (**BKD**) and furunculosis. Bacteria and parasitic diseases found in the Little White Salmon NFH are listed in Tables 16 and 17.

Table 1 (RH-1). Total hatchery returns of tule fall chinook to the Little White Salmon NFH by brood year.

Based on the following tag codes: **05-10-22, 05-15-26**, 07-21-41, 07-21-43, 07-24-24, 07-24-26, 07-25-47, 07-25-07, 07-28-27, 07-28-28, 07-30-07, 07-31-25, 07-31-26, 07-33-17, 05-13-54, 07-30-08, 07-33-18, 07-37-54, 23-20-58, 23-20-59, 23-21-03, 23-21-07, 23-21-16, 23-21-17, 23-21-23, 23-21-25, 23-21-35, 23-21-44, 23-21-45, 23-21-48, 23-21-52, 23-21-56, 23-21-59, 23-21-60, 23-22-03, **23-22-04, 23-22-05, 23-22-07**, 23-22-14, 23-22-17, **23-22-18, 23-22-19, 23-22-22**, 23-22-24, 23-22-25, 23-25-31, 23-25-37, 23-25-49, 23-26-11, 23-26-21, 23-26-38, 23-20-57, **23-20-60**, 23-20-61, 23-21-01, **23-21-04**, 23-21-08, 23-21-10, 23-21-11, 23-21-14, 23-21-15, 23-21-20, 23-21-25, 23-21-27, 23-21-30, 23-21-36, 23-21-43, 23-21-47, 23-21-49, 23-21-50, 23-21-51, 23-21-53, 23-21-54, 23-21-55, 23-21-57, 23-21-58, 23-21-61, 23-21-62, 23-22-06, 23-22-08, 23-22-10, 23-22-11, 23-22-12, 23-22-13, 23-22-16, 07-33-26, 07-36-34, 07-36-35, 07-36-36, 07-37-52, 07-37-53, 07-37-55, 07-43-16, 07-47-22, 07-47-32, 07-47-37, 07-47-37, 07-47-38, **07-47-41**, 07-47-42, 10-26-41, 07-33-18, 07-42-54, 07-43-03, 07-43-17, 07-43-20, 07-47-19, 07-47-19, 07-47-21, 07-47-21, 07-47-25, 07-47-32, 07-47-38, 07-47-41, 07-47-42, 07-50-30, 23-20-55, 23-20-63, 23-21-06, 23-21-09, **23-21-13, 23-21-19**, 23-21-22, 23-21-24, **23-21-31, 23-21-33**, 23-21-34, 23-21-37, 23-21-38, 23-21-39, 23-21-41, 23-21-42, 23-22-01, 23-22-02, 23-22-15, 23-22-20, 23-22-21, 23-25-16, 23-25-28, 23-25-44, 23-25-47, 23-25-56, 23-26-19, 23-26-52, 23-26-62, **23-28-21, 23-28-25**, 23-28-32, 23-28-37, 23-28-41, 23-28-44, 23-28-50, 23-28-52, 23-28-62, 23-31-11, 23-31-16, 23-31-21, 23-31-25, 23-31-26, 23-31-37, 23-31-38, 23-31-41, 23-31-42, 23-31-44, 23-31-47, 23-31-61, 23-31-62, 23-32-01, 23-32-04, 23-32-04, 23-32-07, **B5-03-09, 05-05-28, 07-22-07**, 07-25-06, 07-17-33, 07-17-35, 07-21-43, 07-25-07, 07-16-38, 07-16-61, 07-17-34, 10-22-11, 07-24-24, 07-24-26, 07-25-47, 07-28-27, 07-28-28, and 07-24-25.

Beginning with the 1978 brood.
Some upriver bright coded wire tagged fall chinook were spawned as tules.

Table 7 (AC-1). Age composition percentage (freshwater.ocean) by brood year for tule fall chinook returning to the Little White- Salmon NFH.

Age Composition (%)

Brood Year	N	1.1	1.2	1.3	1.4	1.5	2.1	2.2	2.3

LITTLE WHITE SALMON

Coho

GEOGRAPHIC LOCATION

The Little White Salmon River, located in Skamania County in south central Washington, drains approximately 134 square miles. The river originates in the Gifford Pinchot National Forest, west of Monte Cristo Peak, and travels south for about 19 miles before entering Bonneville Pool on the Columbia River at River Mile (RM) 162, about six miles below the confluence of the White Salmon River and the Columbia. A railroad embankment and highway about one-half-mile below the original mouth of the river cuts off a shallow embayment from the Columbia River and forms 212 acre Drano Lake. Two federal fish hatcheries are located on the river, the Little White Salmon National Fish Hatchery at RM 1 and the Willard National Fish Hatchery at RM 5.

ORIGIN

Coho may have been historically present in small numbers below the barrier falls in the lower river (Bryant 1949). However, after Bonneville Pool inundated the lower river, only hatchery fish have been present.

Subbasin hatchery **coho** rearing presently occurs exclusively at the Willard National Fish Hatchery. Adults and eggs are collected at the Little White Salmon Hatchery, but rearing and release occur at Willard NFH (Little White Salmon Hatchery produces mainly spring chinook). Willard Hatchery was built in 1952 and occupies 80 acres. Early returning **coho** are used at the hatchery. Most existing early **coho** (Type-S) hatchery programs are considered linked to native Toutle River stock who. Washington stations either received Toutle stock eggs or utilized local native early run **coho** (Howell et al. 1985).

DISTRIBUTION

Anadromous fish migration was completely blocked by a series of water falls approximately 37 feet high located about two miles upstream of the Columbia River. Before Bonneville Dam was completed, this short reach supported **coho** salmon. When Bonneville Dam was completed in 1938, this area was inundated and natural salmon production ceased.

PRODUCTION

The Willard National Fish Hatchery produces the only **coho** on the Little White Salmon. The Northwest Power Planning Council's smolt capacity model indicated that a total of 18,709 smolts could be produced using all **subbasin** habitat.

Plants for 1977 through 1986 averaged **2,851,000** smolts and 155,000 fingerlings, although fingerling plants are not annual (WDW, 1990). During 1986 - 1990, 81 percent of the juvenile **coho** releases above Bonneville Dam were into the Little White Salmon and Klickitat Rivers (TAC, 1991).

The Little White Salmon River tributary (Drano Lake) sport catch estimates between 1977 - 1986 **return** years averaged 158 adult **coho**, ranging from a low of 3 in 1977 and a high of 733 in 1982, with a harvest rate of 1.8 percent (WDW, 1990). Estimates are based on punch card totals and limited sampling data. Specific age composition and brood year analyses for the Little White

Salmon River sport catch are unavailable.

Willard Hatchery returns to the Little White Salmon Hatchery rack for the 1984 -1988 brood years averaged 6,057 adults with a low of 2,079 in 1987 and a peak of 10,909 in 1986 based on scale reading analysis performed by U.S. Fish and Wildlife Service. Specific age and brood year analysis for the Little White Salmon are presented in Table 1.

ADULT LIFE HISTORY

Run size, catch and escapement

Little White Salmon **coho** are primarily harvested in the ocean and Columbia River by commercial and sport fisheries. Total harvest rate is about 80 percent.

Ocean commercial and recreational fisheries off the Oregon coast are the primary harvesters of early **coho**. The Oregon troll fishery accounts for the highest percentage of the overall catch (Howell et al. 1985).

Based on coded-wire tagged releases of 1976 - 1978 brood late **coho**, most of the harvest occurs in the Washington and Oregon ocean fisheries. Late **coho** have a more northerly migration pattern than early **coho** (WDF, 1990). This is reflected in the catch distribution where the Washington coastal catch comprised 40 percent of the total harvest compared to 20 percent for early **coho** during 1979 - 1981. Late **coho** also contribute significantly to the lower Columbia River commercial gill net fishery (Howell et al. 1985).

Straying from other hatcheries does occur but is rare. Table 2 lists Willard National Fish Hatchery Hatchery origin **coho** stray coded-wire tag recoveries beginning with the 1978 brood through to the 1988 brood. Table 3 lists the coded-wire tags recovered within the Little White Salmon Hatchery which originated outside the Little White Salmon subbasin.

Harvest rates have averaged 79 percent for Type-S **coho** between 1983 and 1987. Harvest of **Type-S coho** is occasionally constrained by one or more of the fall chinook stocks.

Time of Migration

Early **coho** enter the Columbia River by mid-August and begin returning to the Little White Salmon hatchery in September through the first week of November. In the **mainstem** Columbia River early **coho** predominate from August to mid-September. Stock composition shifts to late **coho** in late September and October.

Spawning Period

Adults are held from late September to late November when they are spawned (WDW, 1990).

Spawning Areas

Willard National Fish Hatchery.

Age composition

An average of 90.4 percent of Willard National Fish Hatchery **coho** return as adults and an average

of 9.6 percent return as jacks. Table 4 shows the age composition percentage (freshwater-ocean) by brood year for **coho** rack returns to the Little White Salmon National Fish Hatchery.

Sex Ratio

Female **coho** comprised 37 to 46 percent of the **coho** returning to the Little White Salmon Fish Hatchery between 1985 and 1987 brood years. The percent females by brood year and freshwater-ocean rearing ages for the Little White Salmon Hatchery returns is presented in Table 5.

The fork length of **coho** returning to the Little White Salmon Hatchery by brood year and age class (**freshwater.ocean**) is presented in Table 6.

Fecundity

Fecundity was once estimated to average 2,100 eggs per female (**USFWS**, unpublished), but a time series of fecundity data for **coho** from the Willard Fish Hatchery by age and brood year is unavailable.

JUVENILE LIFE HISTORY

Time of Emergence

Fry emerge from mid- January to February (**WDW**, 1990).

Time, age and size at migration

Freshwater rearing generally lasts for about 14 months. Hatchery release information for the Little White Salmon **subbasin** by brood year is presented in Table 7. Based on coded-wire tag recovery studies by Dawley et al. (1982), arrival in the Columbia River estuary occurs soon after hatchery release (Howell et al. 1985).

Survival Rate

A survival rate for natural **coho** from the Little White Salmon **subbasin** is unavailable.

BIOCHEMICAL-GENETIC CHARACTERISTICS

Data has not been compiled.

DISEASE

Bacteria and parasitic diseases found in the Willard National Fish Hatchery and Little White Salmon National Fish Hatchery are listed in Table 8 and 9 (**WDF** Salmon Culture, Olympia).

Table 1 (RH). Total hatchery returns of **coho** to the Little White Salmon Hatchery by brood year.

SPRING CREEK NATIONAL FISH HATCHERY

Fall Chinook Salmon

GEOGRAPHIC LOCATION

Spring Creek National Fish Hatchery is located in Skamania County on the Bonneville Pool of the Columbia River at River Mile **(RM)** 167, about a mile below the mouth of the White Salmon River.

ORIGIN

Of the tributaries of the Bonneville Pool, fall chinook were historically native to the Wind, Little White Salmon, Big White Salmon, and Hood Rivers **(Fulton, 1968)**. Now the aggregate upriver fall chinook run is composed of two large stocks, the upriver brights **(URB)** and Bonneville Pool Hatchery stocks **(BPH)**. Both stocks pass over Bonneville Dam. The BPH stock was brought into hatchery production with the first egg-take in 1896 and BPH fall chinook are produced almost entirely by artificial propagation **(Howell et al. 1985)**.

DISTRIBUTION

Some natural production exists in the Klickitat, Wind, Big White Salmon, and Hood Rivers. BPH fall chinook are reared at Klickitat, Little White Salmon, and Spring Creek Hatcheries **(Howell et al. 1985)**.

PRODUCTION

Completion of Bonneville Dam inundated all of the spawning area in the Little White Salmon River and Condit Dam blocked the Big White Salmon.

Hatchery production began in 1896 from eggs collected in the Little White Salmon River **(WDF, USFWS 1951)**. Little White Salmon fall chinook were intermittently planted in many tributaries from the Sandy to the Deschutes River. Within several years of the establishment of the Little White Salmon Hatchery program, other hatchery and egg-take facilities were constructed on the Wind River and Big White Salmon Rivers.

In 1901, fall chinook eggs collected from the Big White Salmon River were transferred to the Spring Creek facility. The initial adult return in 1904 provided the basis for subsequent production. The Spring Creek Hatchery program has been very successful, with surplus eggs transferred to other stations in most years. During the years eggs were transferred to Spring Creek, they came from lower river hatchery **(LRH)** fall chinook stocks **(Howell et al. 1985)**.

Klickitat Hatchery has had a chronic problem of meeting escapement and has utilized stock from Spring Creek Hatchery. BPH fall chinook programs at Little White Salmon and Klickitat Hatcheries have either received eggs directly from Spring Creek or have utilized local returns that are considered to be derivatives of Spring Creek stock **(Howell et al. 1985)**.

Spring Creek Hatchery returns of tule fall chinook "swim-ins" from 1987 through 1984 brood years averaged 10,467 adults with a low of 408 in 1983 and a high of 27,200 in 1978. Hatchery returns of tule fall chinook to Spring Creek Hatchery by age and brood year is presented in Table 1.

Tule fall chinook trapped at Bonneville Dam and trucked to Spring Creek Hatchery totaled 1,547

adults for 1983 and 2,379 adults for 1984. Total hatchery returns of tule fall chinook trapped at **Bonneville** Dam and trucked to **Spring** Creek Hatchery by age and brood year are presented in **Table 2**.

Upriver Bright (**URB**) fall chinook were released from Spring Creek on an experimental basis in 1984 and 1985 brood years. Total age of hatchery returns of bright **fall** chinook to Spring Creek Hatchery by brood year is presented in Table 3.

ADULT LIFE HISTORY

Run size, catch and escapement

Based primarily on the success of Spring Creek Hatchery, BPH fall chinook are a major contributor to the Washington troll, net, and sport ocean fisheries. Coded wire tag recoveries of 1971 and 1972 brood year fingerling releases from Spring Creek Hatchery showed that 38 percent were caught off the Washington coast and 20 percent were caught in the Columbia River sport and commercial harvest (Howell et al. 1985).

From 1979 - 1984 the harvest of BPH fall chinook in freshwater was determined primarily by expansion of coded wire tags collected during fisheries sampling. In 1980 -1984, natural and hatchery escapements were adjusted, based on coded wire tag recoveries for fall chinook straying to non-origin areas. Prior to 1979, catch was determined by applying the 1979 stock specific **pre**-escapement proportion in the fisheries to the particular stock for each year (Howell et al. 1985).

Strays from other hatcheries are quite common. Spring Creek Hatchery origin tule and upriver bright fall chinook stray coded wire tag recoveries beginning with the 1978 brood through the 1990 brood are listed in Table 4. Tables 5 and 6 list coded wire tags of tule and bright fall chinook recovered within the Spring Creek Hatchery, respectively, which originated outside of the Spring Creek Hatchery. Table 7 list coded wire tags of tule and bright fall chinook trapped at **Bonneville** Dam that originated outside the Spring Creek Hatchery and were trucked to the Spring Creek Hatchery.

Time of Migration

Tule fall chinook upstream migration begins in early August with greatest abundance in the Columbia River estuary in late August and early September. Counts of tule fall chinook at Bonneville Dam generally peak between September 4 and September 9. Approximately 90 percent of the run has migrated past Bonneville Dam by September 20 (Howell et al. 1985).

Upriver bright fall chinook migration curve is more prolonged and gradual compared to tule fall chinook passing Bonneville Dam. Adult upriver bright migration occurs through November.

Spawning Period

Tule and upriver bright fall chinook spawning ground peak index counts are usually made during early October and November, respectively. Peak spawning at the Spring Creek Hatchery is mid-September.

Spawning Areas

Spring Creek National Fish Hatchery.

Some natural production of BPH fall chinook occurs in the Wind, Big White Salmon and Klickitat River. A small amount also occurs in Rock Creek and Collins Creek (WDF, 1990).

Age Composition

Ages of tule fall chinook range from two-year-old jacks to five-year-old adults with three-year-olds usually the dominant age classes (Howell et al. 1985). Tables 8 and 9, respectively, present total age composition percentages by brood year and age class for tule fall chinook trapped at Bonneville Dam then trucked to Spring Creek Hatchery, and for tule fall chinook returning to Spring Creek Hatchery.

Although Spring Creek Hatchery adult returns are incomplete, upriver bright fall chinook total ages generally range from two-year-old jacks to six-year-old adult.

Sex Ratio

There is an occurrence of female jacks at Spring Creek Hatchery. Females returning to Spring Creek Hatchery averaged 59.90 percent for the 1979 through 1984 brood years with a low of 50.14 percent for 1979 and a high of 66.37 for 1980. Table 11 presents the percent females by brood year and age (**freshwater.ocean**) for tule fall chinook returning to Spring Creek Hatchery.

The total percent of tule fall chinook females by brood and age class (**freshwater.ocean**) trapped at Bonneville Dam and trucked to the Spring Creek Hatchery is presented in Table 10.

Table 12 presents the percent females by brood year and age class (**freshwater.ocean**) for upriver bright fall chinook returning to the Spring Creek Hatchery.

The mean fork length by brood year, sex, tule, bright, and **freshwater.ocean** rearing ages of Bonneville Dam trapped and Spring Creek Hatchery returns is presented in Tables 13 through 18.

Fecundity

Fecundity averaged 4,700 eggs per female at Spring Creek Hatchery from 1978 - 1982 (Howell et al. 1985).

JUVENILE LIFE HISTORY

Time of Emergence

At Spring Creek Hatchery, water temperatures during incubation are set at approximately 52 degrees Fahrenheit. Newly absorbed yolk-sac fry are prevalent in mid-December (Howell et al. 1985).

Time, age and size at migration

Hatchery release information for the Spring Creek Hatchery by brood year is presented in Table 19. BPH fall chinook are released as fingerlings primarily in March through June. Because of the controlled water temperatures at Spring Creek Hatchery, growth is rapid. Most of Spring Creek production is liberated in March and April, earlier than other hatchery releases of fall chinook. Releases at the Klickitat and Little White Salmon hatchery releases occurs from May through mid-June (Howell et al. 1985).

Based on recoveries of tagged Spring Creek juveniles, -migration to the Columbia River estuary is rapid and generally occurs within 1 - 3 weeks after release. From scale readings, juveniles enter the ocean in the first year of life and are **considered** "sub - 1" age migrants. Size at release varies between 70 - 100 mm in length (Howell et al. 1985).

Survival Rate

BPH fall chinook reared and released from Spring Creek Hatchery are noted for their generally high survival rate. Spring Creek **substock** fall chinook reared at other stations do not experience the same high survival rate. A minimum survival rate (partial catch and escapement) of four groups of coded wire tagged Spring Creek Hatchery releases ranged between zero and 1.9 percent (1978 brood) and 0.3 -2.1 percent (1979 brood) (**Vreeland**, 1984). Survival of the 1979 brood releases were based on only two years of catch. These rates were much higher than the average of 0.2 percent for the 1978 and 1979 brood tule releases from other stations. TAC (1984) estimated a general survival rate of Spring Creek Hatchery releases at 2.0 percent which did not include mortality on juvenile out-migrants caused by Bonneville Dam (Howell et al. 1985).

BIOCHEMICAL-GENETIC CHARACTERISTICS

Schreck et al. (1984) compared isozyme gene frequencies for 11 enzyme systems from samples collected at Bonneville and Spring Creek Hatcheries. No statistically significant differences in gene frequencies were determined for any of the enzymes.

DISEASE

Common diseases at Spring Creek Hatchery includes: Bacterial kidney disease, enteric redmouth, cold water disease, and **furunculosis**. A complete list of bacteria and parasitic diseases found at Spring Creek Hatchery is presented in Table 20 (**WDF Salmon Culture**, Olympia).

Figure 1 (TT). Freshwater life history Bonneville Pool Hatchery fall chinook (tules).

WHITE SALMON SUBBASIN

Naturally Produced Summer Steelhead

GEOGRAPHIC LOCATION

The White Salmon River begins on the southwest slope of Mount Adams in south-central Washington. The river drops from its mountain source through 45 miles of forested hills and river valleys before entering into the Bonneville Pool on the Columbia River at river mile (RM) 168.3. All of the White Salmon River except the Condit project from RM 2.0 to RM 6.0 has been designated "scenic river" a classification designed to protect and preserve the undeveloped, natural condition of this section of river. The river drains a watershed of approximately 386 square miles.

ORIGIN

The wild summer steelhead in the White Salmon River is native, although interbreeding with Skamania and Wells hatchery stocks. Marked steelhead stray into the White Salmon and are caught, but it is unknown if they represent a component of the spawning population.

DISTRIBUTION

Table 1 lists rearing and spawning habitat, by quality, for White Salmon River summer steelhead based on estimates from the Northwest Power Planning Council. Historically, the upper limit for chinook was a series of falls at RM 16.2 (past reports indicate it may have been possible for steelhead to navigate over the falls under ideal conditions). Distribution of all anadromous fish was drastically reduced by the construction of Condit Dam in 1913. Although two attempts were made to ladder the dam, both failed, and without a fishway Condit Dam blocks all fish migration. Steelhead production is limited to the 2.0 miles of river downstream from the Condit Dam powerhouse.

PRODUCTION

Production Facilities

The White Salmon River has no full production hatchery operating in the basin. There are two rearing facilities in the subbasin. Spring chinook are reared at the White Salmon Rearing ponds (RM 1.5), and Northwest Lake net-pens rear steelhead. Both of these facilities release their fish into the White Salmon River.

Production Summary

No data are available on summer steelhead smolt production, Natural smolt production is limited to the lower river. The construction of Condit Dam eliminated over 50 miles of mainstem and tributary spawning and rearing habitat. This includes those miles above a falls at RM 16.2 which were assessable under the right conditions.

ADULT LIFE HISTORY

Run size and Escapement

No estimates of wild run size or escapement is available. Spawner surveys and wild fish harvest

data are incomplete, however, using smolt capacity models and 3 percent smolt to adult return rate, wild fish run size was estimated to be 50 fish (Subbasin Plan 1990).

Time of migration

Adult summer steelhead enter the river in April through December, peaking in July through September.

Harvest

Ocean harvest for summer steelhead is unknown.

Columbia River harvest is comprised of many stocks which migrate through the Columbia River. Both sport and tribal fisheries harvest steelhead in the Columbia River with White Salmon River steelhead likely being part of the harvest.

Sport harvest (mostly “dip-in” fishery) within the White Salmon River occurs below Condit Dam. Sport harvest of summer steelhead (hatchery and wild) from 1977 through 1989 averaged 1,841 fish based on permit-card harvest estimates (Table 2). As of 1986, in order to help protect wild steelhead returns, fishing regulations restrict harvest to hatchery fish only, all wild steelhead must be released.

The White Salmon River attracts a large number of anglers at the mouth of the river. This popular fishery concentrates on “dip-ins” which are generally migrating steelhead from other subbasins temporarily entering the White Salmon River where these fish are caught.

Spawning period

Wild summer steelhead spawning occurs from January through April, peaking in February and March.

Spawning area

Summer steelhead are believed to spawn in the lower 2-3 miles of river. Over 50 miles of White Salmon River steelhead habitat is blocked by Condit Dam.

Fecundity

No data are available on wild steelhead fecundity.

Age composition

One year of limited data showed 80 percent of returning fish belonged to the 2.2 age class. Table 3 outlines age data from return year 1980-81.

Size

No data are available on lengths of wild adult steelhead.

Sex ratio

No data on percent of females within **returning** steelhead adults.

Survival rate

No data are available for the White Salmon River.

JUVENILE LIFE HISTORY

Egg

No data are available on egg production or survival.

Emergence

Wild summer steelhead emergence occurs in **spring** and early summer.

Juvenile rearing

Juvenile rearing for the majority of wild smolts **lasts** approximately two years prior to ocean emigration.

Wild steelhead smolts emigrate in April and May, peaking in early May, at the size of 160 mm.

Hatchery releases

The majority of smolts are reared at Skamania Hatchery and released into the White Salmon River at an age of 14 months. Table 4 outlines hatchery releases into the White Salmon River from 1981 through 1990. In addition to hatchery releases, a net pen operation in Northwestern Lake above Condit Dam rears and releases steelhead into the White Salmon River with releases of 7,200 smolts in 1988 and 20,000 smolts in 1989. These fish were released below Condit Dam at river mile 1.5. The net pen operation is a cooperative project between Washington Department of Wildlife, Pacific Power and Light and a local sport-fishing club, the White Salmon Steelheaders.

BIOCHEMICAL-GENETIC CHARACTERISTICS

No data are available on wild summer steelhead. A number of factors make it questionable as to whether genetically independent wild steelhead still exist in the White Salmon River. Factors such as; blockage of the majority of spawning and rearing habitat, small size of the run, mixing with returning hatchery releases and possible interbreeding with strays from other subbasins (Subbasin Plan 1990).

DISEASES

Table 5 outlines disease history for hatchery summer steelhead released into the White Salmon River.

WHITE SALMON SUBBASIN

Naturally Produced Winter Steelhead

GEOGRAPHIC LOCATION

The White Salmon River begins on the southwest slope of Mount Adams in south central Washington. The river drops from its mountain source through 45 miles of forested hills and river valleys before finally entering into the Bonneville Pool on the Columbia River at river mile (RM) 168.3. All of the White Salmon River except the Condit project from RM 2.0 to RM 6.0 has been designated "scenic river" a classification designed to protect and preserve the undeveloped, natural condition of this section of river. The river drains a watershed of approximately 386 square miles.

ORIGIN

The wild winter steelhead stock in the White Salmon River is native, although interbreeding with Elochoman and Chambers Creek hatchery stocks has likely occurred.

DISTRIBUTION

Table 1 lists rearing and spawning habitat, by quality, for White Salmon River winter steelhead based on estimates from the Northwest Power Planning Council.

Historically, the upper limit for steelhead was a falls at RM 16.3 (past reports indicate it may have been possible for steelhead to navigate over the falls under ideal conditions). Distribution of all anadromous fish was drastically reduced by the construction of Condit Dam in 1913. Although two attempts were made to ladder the dam, both failed, and without a fishway Condit Dam blocks all fish migration. Marked steelhead from many other Columbia River stocks have been recovered in White Salmon fisheries, but if, or the extent of these populations spawning in the river is unknown.

PRODUCTION

Production Facilities

The White Salmon River has no full production hatchery operating in the basin. Two rearing facilities, White Salmon rearing ponds (RM1.5) which grow spring chinook salmon and Northwest Lake net-pens which rear steelhead, both release fish into the White Salmon River.

Production a r y

No data are available on winter steelhead smolt production. Smolt production is limited by loss of upstream habitat which is blocked by Condit dam as well as the construction of Bonneville Dam and the associated flooding of the lower river, hence current steelhead production is undoubtedly reduced relative to past levels. The Northwest Power Planning Council estimate for smolt carrying capacity below Condit Dam was 3,541 smolts (both winter and summer) which divided in half results in 1,771 winter steelhead smolts. Natural smolt production in 1985 for the 1.6 mile reach below Condit Dam was estimated at 5,116 fish (Subbasin Plan 1990).

ADULT LIFE HISTORY

Run size and Escapement

No estimates of wild run size or escapement exist. Little is known about White Salmon River

winter steelhead, biologists have no current or historical data to conclusively prove that a natural winter steelhead run actually exists in the White Salmon River. Evidence to suggest that a natural winter steelhead run exists now or in the past is unclear although hatchery introductions have led to successful returns of winter steelhead to the White Salmon River. Wild winter steelhead run size is considered small, based on smolt production potential 50 wild steelhead were recently estimated to return to the subbasin.

Time of migration

Unknown, although based on fish returning to the Kalama River, steelhead enter the river in April through December, peaking in July through September.

Harvest

Ocean harvest of winter steelhead is unknown.

No data are available for Columbia River harvest.

Sport harvest of this stock occurs below Condit Dam. Sport harvest of winter steelhead from 1970 through 1982 averaged 18 fish annually. Hatchery releases which began in 1982 increased harvest to an average of 177 fish annually from 1983 through 1989 based on permit-card harvest estimates. Table 2 list yearly catch of winter steelhead from 1977 through 1989.

Spawning Period

Wild winter steelhead spawning occurs from March through June.

Spawning area

Winter steelhead are believed to spawn in the lower 2-3 miles of river. Approximately 16 miles of White Salmon River steelhead spawning habitat is blocked by Condit Dam.

Fecundity

No data on wild steelhead fecundity.

Age composition

No data are available on wild winter steelhead.

Size

No data are available for wild adult steelhead.

Sex ratio

No data are available on percent of females within returning adults.

Survival rate

No data are available on winter steelhead.

JUVENILE LIFE HISTORY

Egg

No data on egg production or survival.

Emergence

No data for wild winter steelhead.

Juvenile rearing

Juvenile rearing for the majority of wild smolts lasts approximately two years prior to ocean emigration.

Wild winter steelhead smolts probably emigrate in April and May, peaking in early May, at the size of 160 mm.

Hatchery releases

The majority of winter steelhead smolts are reared at Skamania Hatchery and released into the White Salmon River at an age of 14 months. Table 9 outlines hatchery releases into the White Salmon River from 1981 through 1990. In addition to hatchery releases, a net pen operation in Northwestern Lake above Condit Dam, rears and releases winter steelhead smolts into the White Salmon River. Fish are released below Condit Dam at river mile 1.5. The net pen operation is a cooperative project between Washington Department of Wildlife, Pacific Power and Light and the White Salmon Steelheaders.

Straying

No data on winter steelhead strays.

BIOCHEMICAL-GENETIC CHARACTERISTICS

No data are available on wild winter steelhead. A number of factors such as; blockage of the majority of spawning and rearing habitat, small size of the run, mixing with returning hatchery releases, make it questionable as to whether genetically independent wild winter steelhead still exist in the White Salmon River.

DISEASES

Disease history for hatchery smolts released into the White Salmon River is outlined in the adjoining White Salmon summer steelhead report.

KLICKITAT SUBBASIN

Spring Chinook

GEOGRAPHIC LOCATION

The Klickitat River **subbasin**, located on the east slope of the Cascade Range in south-central Washington, comprises 1,350 square miles in **Klickitat** and Yakima counties and enters the Columbia River at River Mile (**RM**) 180. The Klickitat River is bounded by Mount Adams on the West, the Goat Rocks to the north, and the Sirncoe Mountains on the east. The **Yakima** Indian Reservation comprises a large portion of the upper Klickitat river subbasin. Klickitat Hatchery is located at RM 42.

ORIGIN

Bryant (1949) cited reports of large runs of spring chinook and a significant Indian fishery at Lyle Falls (**RM** 2) prior to about 1920. The history of hatchery production begins with the first release of 11,900 yearlings of unknown stock origin in 1950 (**WDF**, 1951). Spring chinook were trapped from 1952 through 1959 or later at the upper **fishway** (Falls **#5**). Klickitat Hatchery has occasionally released non-local stock spring chinook of Carson, Willamette, and Cowlitz origin (Howell et al. 1985).

DISTRIBUTION

Bryant cited reports that spring chinook once spawned in the West Fork of the Klickitat River which enters the **mainstem** at RM 63, just below Castille Falls. In 1960 through 1962, obstructions were blasted and **fishways** constructed at Castille Falls (**RM** 64) to allow the introduction of anadromous runs to the upper Klickitat River (YIN). Spring chinook redds have been observed in the **mainstem** from the hatchery as far upstream as RM 84 (Stockley, 1979). However, the largest number of redds ever counted above Castille Falls was just 13 in 1971 (Schwartzberg and Roger, 1986). The naturally produced run spawns in the area from Parrott's Bridge (**RM** 49.0) upstream to about McCormick Meadows (**RM** 80.0). The primary spawning area is from Soda Ford (**RM** 60.7) upstream to Castille Falls, a distance of approximately 4 miles (Howell et al. 1985). Spring chinook probably also spawn in the **mainstem** downstream from the hatchery.

PRODUCTION

By 1951, the annual spring chinook run varied from 1,000 adults to 5,000 adults (**WDF** 1951). Spring chinook brood stock were trapped each year from 1952 through 1959 or later at the upper **fishway** (Falls **#5**). Counts at the trap through 1959 ranged from 110 fish to 3,588 fish, but may greatly underestimate the total runs in those years because of the lack of harvest data from the treaty fishery below Falls 5, passage over the falls itself, and off-peak periods when the trap did not operate (**WDF**, 1960). Primary emphasis is on hatchery production although a remnant naturally produced native run originates from the area upstream of Klickitat Hatchery (Howell et al. 1985).

Tables 1 and 2 describe the amount of spawning and rearing habitat by quality, available in the Klickitat River. This data was derived from the Presence/Absence database of Northwest Power Planning Council, 1991.

The Northwest Power Planning Council's estimate of smolt capacity for spring chinook in the Klickitat River **subbasin** is 620,000 smolts.

Klickitat River Hatchery spring chinook returns from 1977 - 1989 return years averaged 1,016 with

a low return of 53 for the 1985 return year and a peak of 3,176 for the 1989 return year. Klickitat Hatchery returns by age and brood year are presented in Table 3.

Klickitat River tributary sport catch estimates between 1977 - 1989 return years averaged 233 spring chinook, ranging from a low of 6 in 1980 to a high of 839 in 1989. Klickitat River tributary sport catch estimates for complete brood years are presented in Table 4.

ADULT LIFE HISTORY

Run size, catch and escapement

Ocean commercial and recreational fisheries from Alaska to Washington, in addition to Columbia River gill net and sport fisheries, all harvest a portion of the Klickitat River origin spring chinook. Most of the Klickitat Hatchery 1976 brood coded wire tagged spring chinook ocean catch occurred in Alaska (26 percent) and British Columbia (45 percent), Washington and Oregon harvest was relatively minor (Howell et al. 1985). Freshwater harvest occurs primarily by recreational anglers and Yakima Indian **dipnet** fishermen operating in the lower portion of the river. Each season's tributary regulations are developed through consultation between the Washington Department of Fisheries and the Yakima Indian Nation. Columbia River sport and commercial fisheries are managed to ensure attainment of hatchery egg-take requirements.

Time of Migration

Klickitat River spring chinook enter the Columbia River primarily in March and April, **generally** after the lower Columbia River winter gill net season. Spring chinook destined for areas upstream of Bonneville Dam usually peak at the dam between April 20 and April 28 but can be earlier during abnormally low flow years or later during high run-off. Migration into the Klickitat River reaches a peak in May and June (Howell et al. 1985).

Spawning Period

Spawning activity peaks in late August and early September. At Klickitat Hatchery spawning commences in mid-August, peaks about September 10, and is completed by the end of September (Howell et al. 1985).

Spawning Areas

The naturally produced run spawns in the area from Parrott's Bridge upstream (**RM 49**) to McCormick Meadows (**RM 80**). The primary spawning area is from Soda Ford (**RM 61**) upstream to Castille Falls (**Rm 64**). Spring chinook probably also spawn in the **mainstem** downstream from the hatchery.

Age Composition

Ages range from two-year-old mini-jacks to six-year-old adults with four-year-olds usually the dominant age class. Age composition data is summarized in Tables 3 through 7.

Sex Ratio

Female comprised 53.3 percent of the adult returns and 43.8 percent of the total returns to Klickitat Hatchery from 1977 through 1987 (YIN).

Fecundity

The fecundity of spring chinook returns to the Klickitat Hatchery from 1977 through 1987 ranged from 3,753 to 5,347 eggs per female with a mean of 4,188 eggs per-female (YIN, 1990). Klickitat River natural spawn and Klickitat Hatchery fecundity data by age and brood year is unavailable.

JUVENILE LIFE HISTORY

Time of Emergence

At Klickitat Hatchery, juvenile development that corresponds to gravel emergence occurs in late November through early December (Howell et al. 1985). No information is available on time of emergence for naturally produced fry.

Time, age and size at migration

Naturally produced juveniles rear in the upper watershed and remain in the river the entire year migrating downstream in the spring as yearlings (Conroy, 1977). On the basis of redd counts from 1975 through 1985, natural smolt production has averaged around 15,000 for that period of brood years (YIN, 1990). Length data of natural spring chinook smolts from the Klickitat River is unavailable.

Smoltification in the hatchery pond begins about April 1. Hatchery 'release information for the Klickitat **subbasin** by brood year is presented in Table 8.

Downstream smolt migration of yearlings occurs immediately after release. Coded wire tagged hatchery spring chinook released on March 30, 1979 were recovered in the Columbia River estuary from April 6, 1979 to June 10, 1979 with a median capture date of April 19, 1979 (Dawley et al. 1979).

Survival Rate

No information is available on the naturally produced population. The 1975, 1977, and 1985 broods released as smolts had an overall egg-to-smolt survival rates of 71 percent to 74 percent. **Smolt-to-adult** return rates to the **subbasin** (including correction for **subbasin** treaty harvest) for the coded wire tagged 1975, 1976, and 1977 broods were 0.73 percent, 0.34 percent and 0.63 percent, respectively (YIN, 1990).

BIOCHEMICAL-GENETIC CHARACTERISTICS

Isozyme gene frequencies of Klickitat Hatchery spring chinook were determined by Milner et al. (1983).

DISEASE

Based on the disease **profile** during 1979 - 1983, enteric **redmouth** and hemorrhagic septicemia infects the Klickitat Hatchery spring chinook (Howell et al. 1985). Returning adults have received two erythromycin injections. Juveniles have received gallimycin in feed to control bacterial kidney disease (YIN, 1990). Bacteria and parasitic diseases found in the Klickitat Hatchery are listed in Table 9. (WDF Salmon Culture, Olympia).

Table 1 (**HB-1**). Estimated amount of rearing -and spawning habitat, by quality, of the Klickitat River spring chinook production area.

KLICKITAT SUBBASIN

Fall Chinook

GEOGRAPHIC LOCATION

The Klickitat River subbasin, located on the east slope of the Cascade Range in south-central Washington, comprises 1,350 square miles in Klickitat and Yakima counties and drains into the Columbia River at River Mile (RM) 180. The river flows north-south toward the Columbia River with Mount Adams on the West, the Goat Rocks to the north, and the Simcoe Mountains on the east. The Yakima Indian Reservation comprises a large portion of the upper Klickitat River subbasin. Klickitat Hatchery is located at RM 42.

ORIGIN

Prior to the **first** hatchery plants of fall chinook in 1946, fall chinook were not found in the Klickitat River subbasin. The usual explanation for this is that Lyle Falls (RM 2) was impassable to chinook during the low water conditions that generally prevail in late summer and early fall (Bryant 1949).

Escapements to Klickitat Hatchery have usually been insufficient to meet egg-take goals. Both Bonneville Pool Hatchery (BPH) and Lower River Hatchery (LRH) fall chinook eggs were used at Klickitat Hatchery for eventual release as smolts into the Klickitat River. LRH stock released into the Klickitat River from 1971 through 1980 included **Cowlitz**, **Toutle**, **Kalama**, **Washougal**, **Bonneville**, **Cascade**, and **Ringold** stock (Howell et al. 1985). Since 1987, fall chinook egg transfers to Klickitat Hatchery have been of upriver bright stock from Priest Rapids and Bonneville Hatcheries due to poor returns of the LRH and BPH stock.

DISTRIBUTION

Currently, both tule and upriver bright fall chinook spawning ground peak index counts occur between the **Klickitat** Hatchery and the Twin Bridges at Rm 18, a distance of approximately 24 miles.

PRODUCTION

With annual releases from Klickitat Hatchery, passage improvements at Lyle Falls in 1952, fall chinook counts to the fish trap at Lyle Falls 5 rose to over 2,000 fish in 1956, and this was probably an underestimate (WDF, 1960). Evidence suggest natural production of tule fall chinook may be still occurring. Though hatchery releases of tule fall chinook ceased in 1986, several age classes have been observed during recent **tule** fall chinook spawning ground surveys.

Table 1 describes the amount of spawning and rearing habitat by quality, available in the Klickitat River. This data was derived from the Presence/Absence database of Northwest Power Planning Council, 1991.

A Northwest Power Planning Council estimate of carrying capacity for fall chinook in the Klickitat River is 843,000 smolts. The Klickitat River from its mouth to Klickitat Hatchery, a distance of 42 miles, was considered to be fall chinook spawning and rearing habitat in calculating smolt carrying capacity.

The current hatchery program sets an on-station release goal of 4 million upriver bright chinook

smolts, the number prescribed by the 1987 United States vs. Oregon Columbia River Fish Management plan.

Between 1970 through 1984 return years, Klickitat River tule fall chinook natural-escapement averaged 673 fish with a low of 128 in 1977 and a high of 1,827 in 1972 (Howell et al. 1985). The Klickitat River tule fall chinook natural spawn escapement for 1980 and 1981 brood years were 187 and 318 fish, respectively. The Klickitat River tule fall chinook natural spawn escapements by age and brood year are presented in Table 2. There were no stream surveys attempted in 1988 due to water turbidity; therefore an accounting of the 1983 through 1986 brood years is incomplete.

The Klickitat River upriver bright fall chinook escapement for 1989 and 1990 return years were 253 and 2,975 fish, respectively. The Klickitat River upriver bright fall chinook natural spawn escapement by age and brood year are presented in Table 3. There were no upriver bright fall chinook stream surveys on the Klickitat River before 1989; therefore brood year information is incomplete.

The Klickitat Hatchery tule fall chinook returns from 1980 through 1984 brood years averaged 107 and ranged from a low of 39 for the 1982 brood to a peak of 198 for the 1983 brood. Klickitat Hatchery tule fall chinook returns by age and brood year are presented in Table 4. No tule or upriver bright fall chinook returned to Klickitat Hatchery from 1988 through 1990.

Klickitat River tributary sport catch estimates from 1977 through 1986 return years average 48 fall chinook ranging from a low of 6 in 1982 to a high of 125 in 1986 (YIN, 1990). A stock specific age and brood year analysis for Klickitat River sport catch is unavailable.

Klickitat River tribal catches from 1977 through 1987 return years averaged 830 fall chinook ranging from a low of 219 in 1989 to a high of 1,392 in 1986 (YIN, 1990). A stock specific age and brood year analysis for Klickitat River tribal catch is unavailable.

ADULT LIFE HISTORY

Run size, catch and escapement

Ocean commercial and recreational fisheries from Alaska to Washington, in addition to Columbia River gill net and sport fisheries all harvest a portion of the Klickitat River origin fall chinook. Six coded wire tagged groups of tule fall chinook from Klickitat Hatchery representing 1976 through 1981 brood years revealed 64 percent of the adults were caught in salt water, 17 percent caught in the Columbia River, and 19 percent in the Klickitat River (YIN, 1990). The Yakima Indian Nation regulates a **dipnet** fishery in the Lyle Falls reach of the Klickitat River. Columbia River sport and commercial fisheries are not managed to ensure attainment of Klickitat Hatchery egg-take requirements.

Strays from other hatcheries are uncommon. Klickitat Hatchery origin tule and upriver bright fall chinook stray coded wire tag recoveries beginning with the 1978 brood through the 1988 brood are listed in Table 5.

Time of Migration

Tule fall chinook upstream migration begins in early August with greatest abundance in the Columbia River estuary in late August and early September. Counts of tule fall chinook at Bonneville Dam generally peak between September 4 and September 9. Approximately 90 percent

of the run has migrated past Bonneville Dam by September 20 (Howell et al. 1985).

Upriver bright fall chinook migration curve is more prolonged and gradual compared to tule fall chinook passing Bonneville Dam. Adult upriver bright migration occurs through November.

Spawning Period

Tule and upriver bright fall chinook spawning ground peak index counts are usually made during early October and November, respectively.

Spawning Areas

Fall chinook spawning occurs intermittently throughout the Klickitat River downstream of the Klickitat Hatchery at RM 42.

Age Composition

Klickitat River tule fall chinook ages ranges from two-year-old jacks to five-year-old adults with three-year-olds or four-year-olds usually the dominant age classes. Klickitat River tule fall chinook age composition is summarized in Tables 2 and 4. The age composition percentages by brood year for tule fall chinook returning to the Klickitat River spawning grounds and hatchery are unavailable due to limited sampling data.

Upriver bright fall chinook ages generally ranges from two-year-old jacks to six-year-old adults. Klickitat River upriver bright fall chinook natural spawn age composition is summarized in Table 3. The age composition percentages by brood year for upriver bright fall chinook returning to the Klickitat River spawning grounds and hatchery are unavailable due to limited sampling data.

Sex Ratio

No data available.

Fecundity

Klickitat River natural spawn and Klickitat Hatchery fecundity data by age and brood year is unavailable.

JUVENILE LIFE HISTORY

Time of Emergence

Data is unavailable.

Time, age and size at migration

Hatchery release information for the Klickitat River **subbasin** by brood year is presented in Table 6. **Length** data of natural fall chinook smolts from the Klickitat River is unavailable. The number of natural juvenile fall chinook **salmon** that migrate from the Klickitat River is also unavailable.

Survival Bate

Six coded wire tagged groups of tule fall chinook were released from Klickitat Hatchery representing the 1976 through 1981 broods. Survival of the tag groups to all fisheries and escapement ranged from 0.058 percent to 1.063 percent while return rates to the **subbasin** ranged from 0.012 percent to 0.153 percent (YIN, 1990).

BIOCHEMICAL-GENETIC CHARACTERISTICS

Fall chinook that return to the Klickitat River **subbasin** presumably have had varied genetic makeup reflecting the contributions of Lower River Hatchery and Bonneville Pool stocks and the recently introduced upriver bright stock (YIN, 1990).

DISEASE

Bacteria and parasitic diseases found in the Klickitat Hatchery are listed in Table 7. (WDF Salmon Culture, Olympia)

Table 1 (**HB-1**). Estimated amount of rearing and spawning habitat, by quality, of the Klickitat River **fall** chinook production area.

Distance/Area	Excellent	Good	Fair ^a	Poor ^a	Unknown	Total	Confidence
Miles (%)	100	0	0	0		43.4	
Acres (%)	100	0	0	0		315.6	

^a Ratings of fair and poor habitat quality may reflect natural physical features such as waterfall barriers, as well as degradation caused by humans.

1987	6	77					
1988	16						

No Klickitat River stream survey attempted in 1988 because of water turbidity.

Age composition is based on scale reading analysis except:

1980 and 1981 return years - No data was available.

1982, 1983, and 1985 return years - Spring Creek National Fish Hatchery age composition was used.

1984 return year - Spring Creek and Little White Salmon National Fish Hatcheries age composition was used.

Table 3 (RN-2). Total age of natural spawn escapement of upriver bright fall chinook returning to the Klickitat River **subbasin** by brood year.

Total Age

1986		253	2,663				
1987	0	294					
1988	18						

No upriver bright fall chinook surveys were made on the Klickitat River before 1989.

Age composition based on scale analysis.

Table 4 (RH). Total returns of tule fall chinook to the Klickitat Hatchery by brood year.

Total Age

Brood Year	2	3	4	5	6	Total	Adult Total
1974							
1975							
1976							
1977				0			
1978			52	1

1984	53	13	0	0	0	66	13
1985	2	0	0	0			
1986	0	0	0				
1987	0	0					
1988	0						

1982 return - does not include 128 adults that might have been spring/summer chinook.

1984 return - does not include 6 mini-jacks considered spring chinook.

1988, 1989, and 1990 return years - No fall chinook returned to Klickitat Hatchery.

Age composition based on scale reading analysis except:

1980 and 1981 return years - No data available.

1982, 1983, and 1985 return years - age composition from Spring Creek Hatchery applied to Klickitat Hatchery return.

1987 return year - natural spawn age composition applied to hatchery return.

Table 5 (AE). Emigration of coded wire tagged fall chinook from the Klickitat River subbasin.

Hatchery/Release Site	Recovery site, Run Year(s)	Recovery Method	Number Sampled	Number Recovered	Total Number Estimated, (PSMFC)
Klickitat Hatchery (tule)	Little White Salmon, 1981	Hatchery	1,497	1	1
Klickitat Hatchery (tule)	Sea Resources Hatchery, 1982	Hatchery	---	1	1
Klickitat Hatchery (upriver bright)	Lyons Ferry Hatchery, 1986	Hatchery	457	1	1

Based on the following tag codes: 63- 19-47 (tule) and 63-21-57 (upriver bright).

Beginning with the 1978 brood.

Table 6 (TR). Hatchery releases of fall chinook salmon into the Klickitat River subbasin sorted by brood year, hatchery and life stage.

KLICKITAT SUBBASIN

Coho

GEOGRAPHIC LOCATION

The Klickitat River subbasin, located on the east slope of the Cascade Range is south-central Washington comprises 1,350 square miles in Klickitat and Yakima counties and drains into the Columbia River at River Mile (RM) 180. The basin trends north-south toward the Columbia River and is bounded by Mount Adams on the west, Goat Rocks to the north, and the Simcoe Mountains on the east. The Yakima Indian Reservation comprises a large portion of the upper Klickitat River subbasin. Klickitat Hatchery is located at RM 42.

ORIGIN

Coho are not believed to be native to the **Klickitat** subbasin. The Klickitat Hatchery was completed in 1952, with reports of 29 adults returning that same year, apparently from earlier releases (YIN). The Columbia River Management Plan calls for 2 million late **coho** smolts and 500,000 early **coho** smolts from Lower Columbia River hatcheries to be released in the Klickitat River (YIN). Since the original agreement, there have been modifications, but the total amount of **coho** transferred remains the same. These plants began in 1988 in addition to the existing Klickitat Hatchery program.

Both early (Type-S) **coho** and late (Type-N) **coho** have been released in the Klickitat River. Type-S hatchery programs are considered to be linked to native Toutle River stock **coho**. Washington stations either received Toutle stock eggs or utilized local native early run **coho**. Late stock **coho** Type-N are informally considered synonymous with **Cowlitz** River stock **coho**. Late stock hatchery programs were developed utilizing Cowlitz River stock, their derivatives, or native late runs. Late **coho** used in most of the current programs are presumably a blend of all of these, although egg transfers from Cowlitz Hatchery occur most frequently (Howell et al. 1985).

DISTRIBUTION

Coho are not believed to be native to the Klickitat. In 1960 through 1962, obstructions were blasted and **fishways** constructed at **Castile** Falls (RM 64) to allow the introduction of anadromous runs to the upper Klickitat River (YIN).

Although only limited surveys have been conducted, Washington Department of Wildlife reported juvenile **coho** in Summit Creek (YIN) and Washington Department of Fisheries has observed large numbers of **coho** spawning in Dofner creek near the mouth of the Klickitat River (WDF 1981).

PRODUCTION

Since 1952, hatchery returns have fluctuated between zero and 4,283 adults. At Lyle Falls 2, **coho** counts peaked at 4,384 fish in 1956 (YIN). Primary interest is solely hatchery production of **coho**. Both early and late **coho** have been reared at the Klickitat Hatchery, and releases of early and late **coho** from other Lower Columbia River hatcheries has occurred. During 1986 - 90, 81 percent of the juvenile **coho** releases above Bonneville have been into the Little White Salmon and Klickitat Rivers (TAC, 1991).

All **coho** production from the Washougal Hatchery shifted to late **coho** in 1985 brood year. The production goal of the Washougal Hatchery is three million fish, with 2.5 million being transferred

to the Klickitat (WDF, 1990). If the Washougal Hatchery is unable to reach production goals other Lower Columbia River hatcheries such as the Cowlitz, Toutle, or Lewis River Hatcheries supplements the difference.

Tables 1 describes the amount of spawning and rearing habitat, by quality, available in the Klickitat River. This data was derived from the Presence/Absence database of the Northwest Power Planning Council, 1991.

The Northwest Power Planning Council's estimate of smolt capacity for **coho** in the Klickitat River **subbasin** is 28,000 smolts.

The Klickitat River tributary sport catch estimates between 1980 - 1988 return years averaged 506 adult **coho**, ranging from a low of 50 in 1980 and a high of 1,624 in 1983 based on catch records and limited actual sampling data. However, specific age and brood year analysis for Klickitat River sport catch is unavailable.

The commercial tribal harvest estimates of **coho** in the Klickitat from 1986 through 1990 return years averaged 7,860 adults with a low of 200 in 1987 and a peak of 23,000 in 1986. These numbers exclude Klickitat catches accounted for in concurrent Zone 6 fisheries. (TAC, 1991).

Klickitat Hatchery return for the 1980 through 1990 return years averaged 118 adults with zero for 1981 through 1985, 1987, 1989, and 1990 and a peak of 779 adults for 1983. Specific age and brood year analyses for the Klickitat River are unavailable.

ADULT LIFE HISTORY

Run size, catch and escapement

For 1977 through 1985, the average return of **coho** to the Klickitat **subbasin** was estimated at 919 fish. The run size for 1986 was 25,954 fish (YIN). Seven coded-wire tagged study groups were looked at for harvest rates. Four of the seven were early **coho** releases with ocean harvest rates of 54 percent, a Columbia River harvest rate of 28 percent, and a 19 percent escapement (YIN). For the remaining three late **coho** study groups, an ocean harvest rate of 76 percent, a Columbia River harvest of 22 percent, and a 2 percent escapement occurred (YIN).

Ocean commercial and recreational fisheries off the Oregon coast are the primary harvesters of early **coho**. The Oregon troll fishery accounts for the highest percentage of the overall catch. Most of the freshwater recreational harvest occurs in the Washington tributaries (Howell et al. 1985).

Based on coded-wire tagged releases of 1976 - 1978 brood late **coho**, most of the harvest occurs in the Washington and Oregon ocean fisheries. Late **coho** have a more northerly migration pattern than early **coho** (WDF, 1990). This is reflected in the catch distribution where the Washington coastal catch comprised 40 percent of the total harvest compared to 20 percent for early **coho** during 1979 - 1981. Late **coho** also contribute significantly to the lower Columbia River commercial gill net fishery (Howell et al. 1985).

Strays from other lower river hatcheries are not unusual. Table 4 lists Klickitat Hatchery origin **coho** stray coded-wire tag recoveries beginning with the 1978 brood through to the 1988 brood. Table 5 lists the coded-wire tags recovered within the Klickitat **subbasin** which originated outside the Klickitat subbasin.

Harvest rates have averaged 79 percent and 85 percent for Type-S and N stocks, respectively, between 1983 and 1987. Harvest of Type-S **coho** is occasionally constrained by one or more of the fall chinook stocks. Harvest of Type-N **coho** is generally not constrained by weak stocks, with hatchery escapement being the only management constraint (WDF, 1990).

Time of Migration

Early **coho** enter the Columbia River by mid-August and begin returning to the lower Columbia hatcheries in early September. In the **mainstem** Columbia River early **coho** predominate from August to mid-September. Stock composition shifts to late **coho** in late September and October. Typically, the late **coho** run begins entering freshwater in mid to late September with mid-October considered the main migratory period in the **mainstem** Columbia River (Howell et al. 1985).

Spawning Period

For Type-S **coho**, both hatchery and natural spawning occurs around late October, while for Type-N **coho** spawning will extend from late November through March, with the bulk being in December and early January (Howell et al. 1985)

Spawning Areas

Klickitat Hatchery and very limited tributaries.

Age composition

Coho return as two-year-old jacks and three-year-old adults. Specific age composition percentage (freshwater.ocean) by brood year for **coho** spawning naturally and hatchery returns are unavailable.

Sex Ratio

For the return years 1978, 1979, 1984, and 1986, the percent of adult males averaged 68.7 percent with a low of zero percent in 1984 and a high of 78.6 percent in 1986. The percent of adult females averaged 18.2 percent with a low of zero percent in 1984 and a high 20.5 percent in 1986. The percent of jacks averaged 13.1 percent with a low of 7 percent in 1986 and a high of 100 percent in 1984 (**Klickitat Hatchery**). The percentage of females by brood year and age class for **coho** spawning naturally and hatchery returns is unavailable.

Fecundity

Klickitat River natural spawn and **Klickitat Hatchery** fecundity by freshwater-ocean rearing and brood year is unavailable.

JUVENILE LIFE HISTORY

Time of Emergence

The juvenile life history for **Klickitat subbasin coho** is similar to that of other stocks in the region with a spring emergence (WDF, 1990).

Time, age and size at migration

Freshwater rearing generally lasts for about 14 months. Hatchery release information for the Klickitat **subbasin** by brood year is presented in Table 2. Based on coded-wire tag recovery studies by Dawley et al. (1982), arrival in the **Columbia** River estuary occurs soon after hatchery release (Howell et al. 1985). Length data of natural **coho** smolts from the Klickitat River is unavailable. The number of natural juvenile **coho** salmon that migrate from the Klickitat River is also unavailable.

Survival Rate

Before the acclimation pond existed at the Klickitat Hatchery, survival rates of two early **coho** groups and three late **coho** groups ranged from 1.478 percent to 2.529 percent (YIN). The two early **coho** groups that were acclimated to the river water had survival rates at 5.837 percent and 5.876 percent (YIN).

BIOCHEMICAL-GENETIC CHARACTERISTICS

Data has not been compiled.

DISEASE

Bacteria and parasitic diseases found in the Klickitat Hatchery are listed in Table 3. (WDF Salmon Culture, Olympia).

Table 1 (HB-1). Estimated amount of rearing- and spawning habitat, by quality, of Klickitat River coho production area.

Distance/Area	Excellent	Good	Fair ^a	Poor ^b	Unknown	Total	Confidence
Miles (%)	20	38	31	11		34.3	
Acres (%)	7	33	19	41		346.2	

^a Ratings of fair and poor habitat quality may reflect natural physical features such as waterfall barriers, as well as degradation caused by humans.

KLICKITAT RIVER SUBBASIN

Naturally Produced Summer Steelhead

GEOGRAPHIC LOCATION

The Klickitat River originates on the east slope of the Cascade Mountains in south central Washington. Starting at an elevation of 4,400 feet the river runs south for 95.7 miles, joining the Columbia River at the Bonneville Pool river mile (RM) 180.4. The Klickitat basin is bound by Mount Adams on the west, the Simcoe Mountains on the east and Goat Rocks to the north. Topography within the basin ranges from rugged mountains in the northern section, to rolling hills and plateaus in the southern section. The entire watershed encompasses 1,350 miles.

ORIGIN

The wild summer steelhead stock in the Klickitat River is native, although interbreeding with introduced **Skamania** hatchery stock has likely occurred.

DISTRIBUTION

Table 1 lists rearing and spawning habitat, by quality, for Klickitat River summer steelhead based on estimates from the Northwest Power **Planning** Council. The Northwest Power Planning Council habitat estimates depend on subjective habitat quality ratings, which are based on limited observations. Washington Department of Wildlife developed a Smolt Density Model which predicts a smolt carrying capacity of 121,871 total smolts.

Distribution of summer steelhead occurs throughout the **mainstem** Klickitat River and in major tributaries including; Little Klickitat River, Mill Creek, White Creek, Trout Creek, Summit Creek and Diamond Fork. The Klickitat River contains two obstacles to fish migration, Lyle Falls (RM 2.2) and Castile Falls (RM 64.2). In 1952, rocks were cleared and a **fishway** constructed on Lyle Falls resulting in improved access to the river upstream. Increasing fish passage above Castile Falls, which actually consisted of a series of eleven consecutive falls, proved much more difficult. The original plan was to increase fish passage by by-passing all eleven falls with a single tunnel 3,200 feet long. In 1960 construction began but due to unforeseen difficulties, construction of the single tunnel was abandoned and a new system consisting of two tunnels with a **fishway** between tunnels was built and operational in 1962. At this time, even with the tunnel **fishway**, aerial surveys conducted in the spring of 1988 showed no steelhead spawning **redds** above Castile falls leading biologists to suggest that Castile Falls is still a serious barrier to summer steelhead. Barriers to steelhead also exist in several of the tributaries which contain falls and cascades near their mouths which impede or prevent fish passage. The Little Klickitat River and the West Fork may be the most significant of tributaries with barriers to steelhead passage.

PRODUCTION

Production Facilities

The Klickitat Hatchery, which produces chinook and **coho** salmon, is located on the Klickitat River at river mile 42.4. No steelhead rearing facility exists on the Klickitat River.

Production Summary

No data are available on natural smolt production. Natural production continues in both the **mainstem** Klickitat and parts of most tributaries. Smolt production in the upper portion of both the river and most tributaries is believed to be reduced due to clogged streams and misplaced culverts from logging activities and/or livestock grazing.

ADULT LIFE HISTORY

Run size and Escapement

Data are limited on wild run size and escapement. Estimates of escapement from 1980 through 1985, based on **redd** surveys and harvest sampling, showed an average escapement of 2,712 steelhead (wild and hatchery; Table 2). Based on age data from 1979 and 1981, approximately one-third of the run is considered wild origin while the remaining two-thirds are hatchery returns.

Time of migration

Adult time of entry for wild summer steelhead is generally from April through December, peaking July through October.

Harvest

Ocean harvest of Klickitat River steelhead is unknown.

The Columbia River supports treaty and sport fisheries which harvest large numbers of steelhead and although the exact number of Klickitat steelhead caught is unknown, some Klickitat River fish are likely part of the Columbia River harvest.

Tribal and sport fishing account for the majority of fish harvested from the Klickitat River. Based on treaty fishing rights, harvest of Klickitat River summer steelhead is divided so that neither the tribal catch or recreational catch shall exceed 50 percent of the aggregate harvestable steelhead. Tribal fishing is concentrated in the lower river, with a dip net fishery at Lyle Falls. Tribal harvest for the period 1977 through 1987 averaged 1,974 fish per year.

Sport fishing is closed in the lower river between river mile 1.5 and river mile 2.2 but remains open throughout the **mainstem** Klickitat and its tributaries. Sport harvest for the period 1980 through 1990 averaged 1,629 fish based on permit-card harvest estimates (Table 2). Wild fish release regulations currently allow only hatchery steelhead to be legally retained by sport anglers while wild steelhead must be released to help increase escapements of native fish.

Spawning period

Wild summer steelhead spawning occurs from January through March.

Spawning area

Wild **steelhead** spawn throughout the Klickitat River and in the lower reaches of many tributaries. Helicopter surveys of spawning areas, which began in the spring of 1988, showed the majority of redds (97) downstream of the Klickitat Salmon Hatchery although counting was difficult upstream of the hatchery as the river flows through a deep canyon between the hatchery and Castile Falls.

Fecundity

No data are available for Klickitat steelhead.

Age composition

Age composition for 440 sport caught fish (wild and hatchery) between 1979 through 1981 showed 32 percent or 151 fish of the sampled catch was of wild origin. Further breakdown of this subsample of wild fish showed 14 percent were 1-ocean fish, 78 percent were 2-ocean fish, 5 percent were 3-ocean fish and 3 percent were repeat spawners ranging from age 3 through 6-ocean fish (Table 4).

Size

Based on the subsample listed above wild steelhead mean fork lengths were 1-ocean fish at 60 cm, 2-ocean fish at 73 cm, 3-ocean fish at 80 cm and repeat spawners at 77 cm (Table 6).

Sex ratio

Data obtained on summer steelhead sampled from 440 sport caught steelhead showed natural fish with 55 percent females, while females comprised 64 percent of the hatchery fish. Table 5 also presents sex ratio from a limited sample of native fish for the years 1980 and 1981.

Survival rate

No data on steelhead smolt to adult survival.

JUVENILE LIFE HISTORY

Egg

No data on egg to smolt survival.

Emergence

No data are available on Klickitat steelhead.

Juvenile rearing

Juvenile rearing for the majority of wild smolts lasts approximately two years prior to ocean emigration. Based on the 151 natural steelhead sampled 1979-1981, 94 percent showed freshwater residence of two years and 6 percent for three years before outmigration.

Wild steelhead smolts emigrate in April and May, peaking in early May, at the size of 160 mm. Table 4 presents data collected from 1990 smolt sampling on tributaries of the Klickitat River.

Hatchery releases

Washington Department of **Wildlife** has planted summer steelhead smolts in the Klickitat River annually since 1960. Skamania Hatchery, located on the Washougal River, is the main source for smolts planted in the Klickitat River. The Skamania stock was developed in the late 1950's from a

combination of wild Washougal River and wild Klickitat River summer steelhead. Table 8 outlines hatchery releases into the Klickitat River from 1981 through 1990.

Data collected on hatchery fish from a 440 fish sample showed 68 percent or 299 fish of hatchery origin. Age composition for hatchery fish was 4 percent were one-ocean fish, 93 percent were two-ocean fish, 2 percent were three-ocean fish and 1 percent were 4+ age or repeat spawners. The four age groups had mean fork lengths of 62 cm, 72 cm, 90 cm and 79 cm, respectively.

Straying

No data are available on Klickitat steelhead.

BIOCHEMICAL-GENETIC CHARACTERISTICS

No data are available on Klickitat River steelhead.

DISEASES

Disease history for hatchery smolts planted in the Klickitat River is presented in Table 9.

Parasite	Skamania	<i>Trichodina</i> sp.
Viral	Skamania	Infectious hematopoietic necrosis (IHN)
Bacterial	Vancouver ^C	<i>Aeromonas salmonicida</i> (Furunculosis)
Bacterial	Vancouver	<i>Flexibacter cytophaga</i> (Coldwater)
Bacterial	Vancouver	<i>Flavobacterium</i> sp.
Bacterial	Vancouver	<i>Renibacterium salmonarium</i> (BKD)
Parasite	Vancouver	<i>Gyrodactylus</i> sp.
Parasite	Vancouver	<i>Hexamita</i> sp.
Parasite	Vancouver	<i>Ichthyobodu</i> sp. (Costia)
Parasite	Vancouver	<i>Ichthyophthirius multifiliis</i> (Ich)
Parasite	Vancouver	<i>Trichodina</i> sp.

^ASummer steelhead smolts released into the Klickitat River were also reared at the Naches Hatchery located on the Yakima River.

^BVancouver Hatchery is located adjacent to the Lower Columbia River at the city of Vancouver.

^CSkamania Hatchery is located on the Washougal River.

Disease history represents pathogens isolated at these hatcheries and not necessarily a disease outbreak.

KLICKITAT SUBBASIN

Naturally Produced Winter Steelhead

GEOGRAPHIC LOCATION

The Klickitat River originates on the east slope of the Cascade Mountains in south-central Washington. Starting at an elevation of 4,400 feet the river runs south for 95.7 miles, joining the Columbia River at the Bonneville Pool river mile (RM) 180.4. The Klickitat basin is bound by Mount Adams on the west, the Simcoe Mountains on the east and the Goat Rocks to the north. Topography within the basin range from rugged mountains in the northern section to rolling hills and plateaus in the southern section. The entire watershed encompasses 1,350 miles.

ORIGIN

The wild winter steelhead stock in the Klickitat River is native.

DISTRIBUTION

Distribution of winter steelhead is unknown.

PRODUCTION

Production Facilities

The Klickitat Hatchery, which rears chinook and coho salmon, is located on the Klickitat River at RM 42.4 No steelhead rearing facility exists on the Klickitat River.

Production Summary

No data are available on winter steelhead smolt production.

ADULT LIFE HISTORY

Run size and Escapement

Howell et al. (1985) and Klickitat Subbasin Production Plan both recognize a winter steelhead run in the Klickitat Subbasin. Data to support the evidence of a winter race is based on bright steelhead being observed in the late winter and early spring steelhead catches. Although annual catches of bright steelhead occur each winter season the wild winter steelhead run is considered small. No accurate data exists on run size or escapement.

Time of migration

Adult winter steelhead migration period is from January through May, peaking in March.

Harvest

Ocean harvest of Klickitat steelhead is unknown.

Columbia River harvest is comprised of many stocks which migrate through the Columbia River.

No data exists on harvest of Klickitat Winter steelhead although some fish are likely part of the Columbia River catch.

Sport harvest of this stock occurs primarily in the lower and middle sections of the **Klickitat** River. Steelhead caught by sport anglers and reported on permit-cards as March and April caught fish are assumed to be wild winter steelhead. Based on the March through April catch period, total harvest ranged from 2 steelhead in 1986 to 105 steelhead in 1981 based on permit-card harvest estimates. In an effort to protect the winter steelhead current regulations prohibit sport fishing from December through May.

Treaty fishing is closed from January through March.

Spawning period

Wild winter steelhead spawning occurs from March through June.

Spawning area

Winter steelhead are believed to spawn in the lower portion of the Klickitat River.

Fecundity

No data are available on Klickitat **steelhead**.

Age composition

No data are available on Klickitat steelhead.

Size

No data are available on Klickitat steelhead.

Sex ratio

No data are available on Klickitat steelhead.

Survival rate

No data are available on Klickitat steelhead.

JUVENILE LIFE **HISTORY**

Egg

No data on egg production or survival.

Emergence

No data are available on Klickitat steelhead.

Juvenile rearing

Juvenile rearing for the majority of wild smolts lasts approximately two years prior to ocean emigration.

Wild steelhead smolts emigrate in April and May, peaking in early May, at the size of 160 mm.

Straying

No data on Klickitat River steelhead.

BIOCHEMICAL-GENETIC CHARACTERISTICS

Although no data exists on the winter stock, managers would like to protect the genetic integrity of the winter race. In this effort, 1) there has never been supplemental releases of winter hatchery steelhead smolts into the Klickitat River, and 2) continuation of closures for winter steelhead harvest, and 3) closely monitor the summer steelhead smolt release program to minimize potential impacts that summer steelhead may have on genetic make-up of the winter race.

DISEASES

No data are available on Klickitat steelhead.

Appendix Table 3. Columbia River chinook electrophoretic data from Schreck et al. (1936).

Isozyme gene frequencies and sample sizes (N) as determined by electrophoresis for-chinook salmon stocks in Oregon, Washington and Idaho. Numbers at the top of each column are the relative mobilities for each allele present in the enzyme system. Minus signs indicate cathodal migration. An asterisk indicates that an allele was present at a frequency of less than .005. "Form" is the time of freshwater entry (S for spring, F for fall and SUM for summer). A pound sign (#) indicates that data for that stock was obtained from the Genetic Stock Identification Study (Milner et al. 1983).

Chinook salmon gene frequency data (continued).

Appendix Table 4. Columbia River steelhead electrophoretic data from Schreck et al. (1986).

Isozyme gene frequencies and sample sizes (**N**) as determined by electrophoresis for steelhead trout stocks in Oregon, Washington and Idaho. Numbers at the top of each column are the relative mobilities for each allele present in the enzyme system. Minus signs indicate cathodal migration. An asterisk indicates that an allele was present at a frequency of less than .005. "**Form**" is the time of freshwater entry (S for summer and W for winter). A pound sign (#) indicates that data for that stock was obtained from the Genetic Analysis of Columbia River Steelhead Trout (Wishard and Seeb 1983) prepared for the Idaho Department of Fish and Game.

Steelhead trout gene frequency data (continued).
